

# CONTATTO MCP 4

## **Programmable Control Module**

## **User's Manual**

Release 1.2 - October 2018

## *INDEX*

| A1- LIST OF REVISIONS OF THIS MANUAL   | 4  |
|--|----|
| A2- RECOMMENDATIONS  | 4  |
| A3- NEWS OF MCP 4 AGAINST MCP XT AND AVAILABLE VERSIONS                          | 5  |
| 1- MAIN FEATURES   |    |
| 1.1- Required Hardware and Software tools  |    |
| 1.2- Main features of MCP 4  |    |
| 1.3- Terminology and syntax  |    |
| 2- EQUATIONS: TYPES AND SYNTAX   |    |
| 2.1- Equations for the system configuration                                      |    |
| 2.1.1- Configuration of the modules.   |    |
| 2.1.2- Power ON status   |    |
| 2.1.3- Status of fault input modules   | 8  |
| 2.1.4- Communication Protocol  | 9  |
| 2.1.5- Address of MCP 4  | 11 |
| 2.1.6- Identifier of MCP 4   | 11 |
| 2.1.7- Directive for the calculation of sunrise, sunset and sun position         | 11 |
| 2.1.8- Publishing on the bus the status of virtual points and value of registers |    |
| 2.1.9- Management of fault modules   |    |
| 2.1.10- Alignment of the outputs   |    |
| 2.1.11- Data exchange between MCP 4 controllers                                  |    |
| 2.1.12- Number of nodes in a MCP 4 network                                       |    |
| 2.1.13- Scheduler  |    |
| 2.2- Event triggered Equations   |    |
| 2.2.1- Logic equations   |    |
| 2.2.2- SET – RESET equations   |    |
| 2.2.3- TOGGLE equations  |    |
| 2.2.5- THRESHOLD Equations   |    |
| 2.2.6- TIMER Equations   |    |
| 2.2.7- Equations for mathematical and logic calculation                          |    |
| 2.2.8- Equations for binary code generation                                      |    |
| 2.2.9- Equations for recording status changes (EVENT)                            |    |
| 2.2.10- Equations for recording value changes (LOG)                              |    |
| 2.2.11- Management of the external counter modules (ModCNT)                      |    |
| 2.2.12- Management of DALI module (ModDALI)                                      |    |
| 2.3- Time triggered Equations  |    |
| 2.3.1- Scheduler Equations   | 27 |
| 2.4- Macro   | 29 |
| 3- SCRIPT  | 31 |
| 3.1- Summary   | 31 |
| 3.2- Keywords and syntax   | 32 |
| 3.2.1- Using the TRIGGER   |    |
| 3.2.2- VAR, GLOBAL VAR and EXTERN VAR  |    |
| 3.2.3- Logic and Mathematical operations   |    |
| 3.2.4- IFTHENELSEENDIF   |    |
| 3.2.5- CARRY and ZERO  |    |
| 3.2.6- DEFINE  |    |
| 3.2.7- GOTO  |    |
| 3.2.8- SUBROUTINES and FUNCTIONS   |    |
| 3.2.9- BIT(x)  |    |
| ס.ב. זט- איטואט(ג) מוע איוונפוס  | 42 |

| 3.2.11- @RAM k and @WORD k   | 43 |
|--|----|
| 3.2.12- SWAP(x)  | 43 |
| 3.2.13- RANDOM(0)  | 43 |
| 3.2.14- BMASK(x)   | 44 |
| 4- PROGRAM WRITING   | 45 |
| 4.1- Rule for program writing  | 45 |
| 4.2- Compiling the program   | 47 |
| 4.3- Uploading the program to MCP 4 memory                                   | 47 |
| 5- SETTING UP  | 48 |
| 5.1- Connections   | 48 |
| 5.2- Baud Rate selection   | 49 |
| 5.3- TCP/IP parameters settings (Ethernet)                                   | 50 |
| 5.4- RS232 and RS485 serial ports of MCP 4                                   | 51 |
| 5.5- WEBS communication port   | 51 |
| 6- DIAGNOSTICS   | 52 |
| 6.1- Diagnostics of CONTATTO system through MCP 4                            | 52 |
| 7- TECHNICAL CHARACTERISTICS   | 53 |
| 8- OUTLINE DIMENSIONS  | 53 |
| 9- FXP-XT COMMUNICATION PROTOCOL   | 54 |
| 9.1- Messages format ad meaning  |    |
| 9.2- RAM memory mapping  |    |
| 9.2.1- Main RAM memory mapping   |    |
| 9.2.2- RAM mapping of the Scheduler  |    |
| 10- MCP IDE: INTEGRATED DEVELOPMENT ENVIRONMENT FOR APPLICATIONS USING MCP 4 | 60 |
| 10.1- Description of the software package                                    | 60 |
| 10.2- MCP IDE  | 60 |
| 10.2.1- MCP IDE  | 64 |
| 10.2.2- Program transferring   |    |
| 10.3- MCP VISIO  |    |
| 10.3.1- The Groups of MCP VISIO  |    |
| 10.3.2- The Projects of MCP VISIO  |    |
| 10.3.3- The Simulator of MCP VISIO   |    |
| 11- MODBUS COMMUNICATION PROTOCOL  |    |
| 11.1- Abstract   |    |
| 11.2- Supported MODBUS functions   |    |
| 11.3- Example of MODBUS functions  |    |
| 11.3.1- Function 1: Reading the digital output status                        |    |
| 11.3.2- Function 2: Reading the digital input status.                        |    |
| 11.3.3- Function 3: Reading the registers (RAM memory)                       |    |
| 11.3.4- Function 4: Reading analog inputs.                                   |    |
| 11.3.5- Function 5: Command of a single output digital point                 |    |
| 11.3.6- Function 6: Writing a single register (RAM memory)                   |    |
| 11.3.7- Function 16: Writing multiple registers (RAM memory)                 |    |
| 11.4- Tables for relationship Words-Parameters of MCP 4                      |    |
| 11.4.1- Physical inputs  |    |
| 11.4.3- Virtual points   |    |
| 11.4.4- Registers  |    |
| 11.4.5- Counters   |    |
|  |    |

#### A1- LIST OF REVISIONS OF THIS MANUAL

| Rel. 1.0 |            | First emission (MCP 4)   |
|----------|------------|--|
| Rel. 1.1 | Par. 2.1.4 | MODBUS directives better explained   |
| Kei. I.I | Par. 5.3   | TCP/IP parameter settings better explained   |
| Rel. 1.2 | Par. 1.2   | Added special virtual points V2020 to V2027 (communication lost on ETH port)                     |
|          | Par. 2.1.4 | Added information about the management of supported MODBUS MASTER functions                      |
|          | Par. 11.2  | Added function 4 to functions supported by MCP 4 in MODBUS MASTER mode (in addition to 3 and 16) |
|          |            |  |

#### A2- RECOMMENDATIONS

**WARNING:** this manual applies to MCP 4 with the following firmwares:

Main microcontroller: 2.3 or higher Secondary microcontroller: 1.1 or higher

The features described in this manual require the program MCP IDE release 3.2.9 or higher.

This manual assumes that the user have an adequate knowledge about the CONTRITO bus system.

#### Correct disposal of this product

(Waste Electrical & Electronic Equipment)

(Applicable in the European Union and other European countries with separate collection systems). This marking on the product, accessories or literature indicates that the product should not be disposed of with other household waste at the end of their working life. To prevent possible harm to the environment or human health from uncontrolled waste disposal, please separate these items from other types of waste and recycle them responsibly to promote the sustainable reuse of material resources. Household users should contact either the retailer where they purchased this product, or their local government office, for details of where and how they can take these items for environmentally safe recycling. This product and its electronic accessories should not be mixed with other commercial wastes for disposal.

Specifically about the battery, check local regulations for correct disposal. Never use municipal waste.

#### Installation and use restrictions

#### Standards and regulations

The design and the setting up of electrical systems must be performed according to the relevant standards, guidelines, specifications and regulations of the relevant country. The installation, configuration and programming of the devices must be carried out by trained personnel. The installation and the wiring of the bus line and the related devices must be performed according to the recommendations of the manufacturers (reported on the specific data sheet of the product) and according to the applicable standards. All the relevant safety regulations, e.g. accident prevention regulations, law on technical work equipment, must also be observed.

#### Safety instructions

Protect the unit against moisture, dirt and any kind of damage during transport, storage and operation. Do not operate the unit outside the specified technical data. Never open the housing. If not otherwise specified, install in closed housing (e.g. distribution cabinet). Earth the unit at the terminals provided, if existing, for this purpose. Do not obstruct cooling of the units. Keep out of the reach of children.

#### Setting up

The physical address assignment and the setting of parameters (if any) must be performed by the specific softwares provided together the device or by the specific programmer. For the first installation of the device proceed according to the following guidelines:

- Check that any voltage supplying the plant has been removed
- Assign the address to module (if any)
- Install and wire the device according to the schematic diagrams on the specific data sheet of the product

Rel.: 1.2 October 2018

Only then switch on the 230Vac supplying the bus power supply and the other related circuits

#### Applied standards

This device complies with the essential requirements of the following directives: 2004/108/CE (EMC) 2006/95/CE (Low Voltage) 2002/95/CE (ROHS) EN 55022 Class B

#### Note

Technical characteristics and this data sheet are subject to change without notice.

## A3- NEWS OF MCP 4 AGAINST MCP XT AND AVAILABLE VERSIONS

#### Hardware:

- · Fastest processors and memories
- Added one RS485 communication port (COM4)
- Added Ethernet connection
- · Removed alarm relay

#### Functions:

- Integrated weekly Scheduler for management of 16 points ("zones") with 8 time slots each one; each time slot can be individually enabled or disabled
- A new program transferred to MCP 4 is stored in a different memory location and therefore, during the download, the program previously loaded continues to operate without interruption; only when downloading of the new program is completed, and if everything goes well, the automatic switch from the old program to the new one will be performed.
- MODBUS TCP/IP Slave on ETH port
- Integrated Ethernet Bridge, multi-user up to 8 simultaneous connections
- Integrated WEB Server, multi-user up to 8 simultaneous connections, including sceneries management
- Simple Diagnostic through a WEB browser, therefore without need to install MCP IDE program

The available versions are the following:

MCP 4/STD: 1 RS232 + 2 RS485

MCP 4/ETH: 1 RS232 + 2 RS485 + ETH

#### 1- MAIN FEATURES

## 1.1- Required Hardware and Software tools

To use **MCP 4**, the software tools MCP IDE is required, running on a PC (WXP, W7, W8). Minimum hardware required: 1000 MHz processor and 512 Mbytes minimum RAM.

MCP IDE software tools also provides MCP Visio program, allowing to display in a graphical way the status of the field and all parameters of MCP 4, and other programs allowing specific function.

#### 1.2- Main features of MCP 4

- 2032 virtual digital points
- 1024 16-bit registers
- 1024 16-bit counters
- 512 16-bit timers
- 127 real input addresses up to 4-channel 16-bit each one
- 127 real output addresses up to 4-channel 16-bit each one

#### Special virtual points:

- V2032: when set to 1, MCP 4 suspends the equations calculation and the execution of the scripts; when reset to 0, the activity of MCP 4 restarts normally. The point V2032 will be however automatically reset to 0 after a timeout
- V2020 ÷ V2027: it becomes active in case of communication failure for more than 10 seconds on the relative socket 1 ÷ 8 of the ETH port
- V2019: the activation of this point causes the reset and the re-initialization of Ethernet interface
- V2018: activated when a communication loss on COM4 (RS485) occurs for more than 5 seconds
- **V2017**: activated when one or more MODBUS slaves do not answer to MCP 4 (set in MODBUS master mode) for more than 50 retries; it will be deactivated after a full polling cycle to slave devices without errors
- V2016: activated when the communication with WEBS fails
- V2015: reserved, new data are present in the NOTIFY buffer
- V2014: activated during times from sunrise to sunset
- **V2013**: reserved
- V2012: activated when a communication loss on COM2 (RS485) occurs for more than 5 seconds
- V2011: activated when a communication loss on COM1 (RS232) occurs for more than 5 seconds
- V2010: activated 0.5 seconds after the end of initialization procedure
- V2009: the buffer of analog event (LOG or LOGC) is full or old events have been overwritten
- V2008: the buffer of binary event (EVENT or EVENTC) is full or old events have been overwritten
- V2007: reserved
- V2006: reserved
- V2005: error during the execution of a script (e.g. not valid instruction)
- **V2004**: timeout during the execution of a script (>500msec)

- V2003: 1sec period clock (toggle its status every 0.5 seconds)
- V2002: bus failure
- V2001: module failure

## 1.3- Terminology and syntax

In this manual, some symbols and notations will be used; the meaning of these is here bottom explained.

#### General:

DI real or virtual digital input

DO real or virtual digital output

AI analog input or generic register

AO analog output or generic register

Ri generic register

#### Addresses, channels, points:

o3.1 point 1 of output 3 (channel 1) o3:1.1 exactly as the previous one

o3:1.2 point 2 of channel 1 of output module 3

AO15:1 channel 1 of output module 15 AI20:2 channel 2 of input module 20

R12 register R12

B14.5 bit 5 of register R14 (for script only)

v100 virtual point 100

v17..v32 all virtual point from V17 to V32

03:1.1..04:2.16 all output points from O3:1.1 to O4:2.16

#### Numbers:

328 decimal number 0b0001010011111011 16-bit binary number 0b11110010 8-bit binary number

0x14FB 16-bit hexadecimal number

Note: the channel of an input or output module, if not specified, will be assumed 1.

## 2- EQUATIONS: TYPES AND SYNTAX

## 2.1- Equations for the system configuration

## 2.1.1- Configuration of the modules

Specify the module installed in the system (see MCP IDE Keyword List).

```
MOD8I/A = (I1)

MOD8I/A = (I2), (I3)

MOD8R = (O11)

MOD4-4R = (I4, O12)

MOD2DM = (I13, I14, O13, O14)

MOD2DM = (I15, I16, O15, O16)
```

#### 2.1.2- Power ON status

Specify the status or value assigned to outputs or registers at power up or at reset.

R12=- means that R12 maintains the value before the power down (RAM has a battery for back-up)

A016..A017 = 247 means that outputs A016 channel 1, channel 2, channel 3, channel 4 and A017 channel 1 will be set to the value 247 at the power ON. To specify all channels of module 16 and all channels of module 17, the correct equation is: A016:1..A017:4 = 247.

## 2.1.3- Status of fault input modules

Rel.: 1.2 October 2018

The status assumed by MCP 4 for a failed input module; if not specified, MCP 4 assumes the last available value.

#### 2.1.4- Communication Protocol

Set the communication protocols to be used for each port of MCP 4. COM1 is the communication port on the front panel (RS232), COM2 and COM4 are on the terminal block (RS485), COM3 is the special port under the terminal cover on bottom left side (e.g. for WEBS module connected by a flat cable) and LAN1 is the Ethernet port (MCP4/ETH only); on the ETH port, both MODBUS TCP/IP and RTU will be activated (automatic detection). The directives are the followings (FXPXT can be omitted because however activated):

```
COM1 = (FXPXT, MODBUS) // RS232
COM2 = (FXPXT, MODBUS) // RS485
COM3 = (FXPXT, MODBUS) // Dedicated port (WEBS)
COM4 = (FXPXT, MODBUS) // RS485
LAN1 = (FXPXT, MODBUS) // ETH port
```

The available options for all 4 COM ports (COM3 through WEBS module) are the following:

**FXPT** proprietary protocol, <u>always active even if not specified</u>

MODBUS RTU protocol: full correspondence between the number of the Word specified in

the Master MODBUS driver and the number of the Words listed in the RAM map in this own

manual. This is the preferred option.

MODBUS RTU protocol: the number of the Word specified in the Master MODBUS driver

must be increased by 1 in respect to what listed in the RAM map in this own manual. For

compatibility only when replacing a MCP Plus with a MCP 4 in old installations.

#### **MODBUS MASTER**

MCP 4, by the just described directive, behaves as a SLAVE device in a MODBUS network. Alternatively, the MODBUS **MASTER** mode can be activated for MCP 4, exclusively on COM4, using the following directive:

```
MODBUS a (T, Vm) = (Wx, n, Ry, \
.....)
```

#### where:

- a is the address (in the range 1 to 31) of the MODBUS SLAVE node to communicate with
- is the communication timeout in milliseconds; if omitted, the default is 1000 (1 second)
- vm is the virtual point that is activated if the slave "a" does not answer to MCP 4; this parameter is optional and can be omitted. The cumulative point V2017 is always available, see paragraph 1.2
- x is the number of the first MODBUS Word to be read/written
- n is the number of Words to be read/written
- y is the starting number of MCP register where the Words have to be stored

The same directive allows the writing of the specified Words when the value of the related register is modified (by program, script, supervisor, etc.). If more blocks of non consecutive Words have to be read/written on the same MODBUS peripheral device, more lines can be added as follows:

```
MODBUS a (T, Vm) = ( Wx, n, Ry, \ Wj, m, Rk, \ .....)
```

Note: if MODBUS MASTER has been activated, all SLAVE protocols (FXPXT included) on COM4 will be deactivated.

To communicate with more MODBUS peripheral devices, add a directive for each SLAVE address as in the following example; the timeout MUST be the same for all nodes.

```
MODBUS 1 (500)
                = ( WO,
                          10, R101, \
                    W100, 10, R111 )
MODBUS 2 (500)
                = ( W0,
                          10, R121, \
                    W100, 10, R131 )
MODBUS 3 (500)
                  ( WO,
                          10, R141, \
                    W100, 10, R151 )
MODBUS 4 (500)
                = ( WO,
                          10, R161, \
                    W100, 10, R171)
```

Regarding the functions used by MCP4 in MODBUS MASTER mode, the following rules apply:

- If the specified WORD number is in the range 00000 to 30000, MCP4 performs reading via function 3 (Read Holding Registers) and writing via function 16 (Write Multiple Registers). The words read/written are those mapped from WORD 00000 to 30000 in the slave
- If the specified WORD number is in the range 30001 to 39999, MCP4 performs reading via function 4 (Read Input Registers) and no writing (being "Input" registers, thus read only). The words read are those mapped from WORD 0000 to 9998 in the slave
- If the specified WORD number is in the range 40001 to 49999, MCP4 performs reading via function 3 (Read Holding Registers) and writing via function 16 (Write Multiple Registers). The words read/written are those mapped from WORD 0000 to 9998 in the slave
- If the specified WORD number is in the range 50001 to 65535, MCP4 performs reading via function 3 (Read Holding Registers) and writing via function 16 (Write Multiple Registers). The words read/written are those mapped from WORD 9999 to 25534 in the slave

The following table resumes what just listed:

| Word in the directive MCP 4 | Word in the slave | Used MODBUS function |
|-----------------------------|-------------------|----------------------|
| 00000 ÷ 30000               | 00000 ÷ 30000     | 3 [R] and 16 [W]     |
| 30001 ÷ 39999               | 0000 ÷ 9998       | 4 [R]                |
| 40001 ÷ 49999               | 0000 ÷ 9998       | 3 [R] and 16 [W]     |
| 50000 ÷ 65535               | 9999 ÷ 25534      | 3 [R] and 16 [W]     |

#### Notes:

• The numbers shown in the previous table are all in decimal format.

Rel.: 1.2 October 2018

• The first case (Word 00000 ÷ 30000) may seem redundant because it is already included in the last two, and in fact it is, but allows the back compatibility with FW versions of MCP 4 less than 1.7.

#### 2.1.5- Address of MCP 4

Assign an address to MCP 4; allowed values: 1 to 255. It is mandatory when using MODBUS protocol.

```
ADDRESS = (12)
```

#### 2.1.6- Identifier of MCP 4

Assign an identification string to MCP 4 (max 63 characters).

```
ID = (Building 1 controller)
```

## 2.1.7- Directive for the calculation of sunrise, sunset and sun position

MCP 4 can calculate every day the times of sunrise and sunset and the sun position (azimuth and elevation); the calculated values will be loaded into 4 registers that must be defined through the **LOCALIZE** directive here described. For these calculations, the data related to the position has to be provided to MCP 4 (Longitude and Latitude) together to the related time zone (e.g. for Italy this value is 1).

In addition, MCP 4 handles the virtual point v2014, activating it when the current time is inside the range from sunrise to sunset, corrected, if needed, by an amount of minutes that can be declared in the **SUNRISE** and **SUNSET** parameters.

```
LOCALIZE = ( \
    LONGITUDE = 8.8638, \
    LATITUDE = 45.3036, \
    TIMEZONE = 1, \
    SUNRISE = ( 0, R1 ), \
    SUNSET = (0, R2 ), \
    AZIMUTH = R3 , \
    ELEVATION = R4, \
)
```

where:

**LONGITUDE** allowed values in the range -180.0000 to +180.0000 allowed values in the range -90.0000 to +90.0000

**TIMEZONE** in respect to Greenwich: allowed values in the range -12 to +12

SUNRISE minutes to be added or subtracted to the sunrise time (in the range -127 to +127) and the

(optional) register reporting the calculated sunrise time

SUNSET minutes to be added or subtracted to the sunset time (in the range -127 to +127) and the

(optional) register reporting the calculated sunset time

**AZIMUTH** (optional) register reporting the azimuth of the sun; value in the range 0 to 360 reporting the

angular position of the sun in respect to North, measured clockwise in degrees. For instance,

azimuth=90 means that the sun is located to East

**ELEVATION** (optional) register reporting the elevation of the sun; 2's complement value, the register

will contain a value 65446 to 65535 for negative values and 0 to 90 for positive values, corresponding to a value in the range -90 to +90 reporting the position of the sun in respect to the horizon, measured in degrees. A positive value means that the sun is above the horizon, a negative value means that it is under the horizon. Elevation=0 means that the sun is exactly

Rel.: 1.2 October 2018

at the horizon line

The times related to sunrise and sunset will be reported by the specified registers as value corresponding to the number of minutes of the day starting from 0:00 (e.g.: 1439 = 23:59).

**Note:** the 4 registers can be optionally declared; this means that, if the calculation of sunrise, sunset and sun position is not required, these ones can be omitted; in this case the virtual point v2014 will be however handled.

# 2.1.8- Publishing on the bus the status of virtual points and value of registers

MCP 4 can be set to send ("publish") on the bus the status of some virtual points and the value of some registers. TO enable the function for the publishing of virtual point and registers, the following instructions has to be added to the MCP 4 configuration:

```
SHARE = ( Vx .. Vy )
SHARE = ( Ri .. Rj )
```

 $v_x$  and  $v_y$  specify respectively a starting and an ending virtual point; for any entered value as  $v_x$  and  $v_y$ , these one will be however forced to values multiple of 16 by the compiler of MCP IDE, therefore, specifying for example  $v_3 ... v_9$ , the compiler will force to  $v_1 ... v_16$ .

Ri and Rj specify respectively a starting and an ending register; these two value can be freely assigned.

Up to 32 SHARE instruction can be added to the same MCP 4 program; each SHARE instruction must contain no more than 128 virtual points or 8 registers.

The SHARE instruction is useful, for instance, when a ModGSM3 module has been installed in the system and it must manage the information related to the virtual points and registers of MCP 4.

**Example.** The following instructions will enable the publishing on the bus of virtual points 1025 to 1280 and of the first 32 registers of MCP 4:

```
SHARE = ( V1025 .. V1152 )

SHARE = ( V1153 .. V1280 )

SHARE = ( R0.. R7 )

SHARE = ( R8.. R15)

SHARE = ( R16.. R23)

SHARE = ( R24.. R31)
```

## 2.1.9- Management of fault modules

Assign a virtual point to the failure condition of one or more modules.

```
MODFAIL(V10) = (I1, I2, O1, O2, O41)

MODFAIL(V11) = (I44)
```

## 2.1.10- Alignment of the outputs

MCP 4 cyclically executes, in addition its many activities, a status request to the output modules (both digital and analog ones); if MCP 4 detects a mismatch between the status or the value read from the field and the related value stored in the RAM memory of the controller, then it must execute an alignment between the field and the RAM. Two alignment directions are available:

the status or the value in the RAM will be transferred to the field output

Rel.: 1.2 October 2018

> the status or the value of the field output will be transferred to the RAM memory

As default, MCP 4 executes the first alignment type (from RAM to field); in some cases (depending on the module type and on the specific application) it is instead preferred, if not mandatory, the second alignment type (from field to the RAM). To specify which outputs must be managed according to this alignment type, the equation **FIELDtoram** must be used. This equation can include single output points, whole values or point intervals as in the following example.

The alignment from field to RAM, however, is not allowed for all types of modules; when allowed, the related technical sheet of the module will specify this, together to some suggestion on the best setting. Remember that, unless otherwise specified in the **FIELDtoram** equation, the alignment will be always executed from RAM to field.

## 2.1.11- Data exchange between MCP 4 controllers

If more MCP 4 controllers have been installed in a plant, it is possible to activate feature allowing to exchange of data among them. To do this, simply connect each MCP to the other, in order to create a RS485 network (exclusively using COM2 port), and instruct each MCP 4 belonging to this network to "publish" the data well specified by proper directives; therefore, non more components are needed in addition to the RS485 cable connecting the installed MCP 4 controllers.

Moreover, the data exchange mechanism here described also applies between **EDITITIO** MCP 4 controllers and **Domino** DFCP controller, allowing interactions between the two systems.

The information that can be published on the network are the virtual points and the registers and therefore, since any digital or analog variable can be supported by these ones, almost any information regarding each MCP 4 or the modules connected to it can be transferred.

Each MCP 4 can publish a maximum of 125 Words; since each register takes 1 Word and a Word can contains 16 contiguous virtual points, as an example the following combinations are allowed:

- 2000 virtual points 0 registers
- 1000 virtual points 62 registers
- > 512 virtual points 93 registers
- > 0 virtual points 125 registers

In other words, the number of virtual points divided by 16, added to the number of register, must be less or equal to 125:

```
(nr.V) / 16 + nr.R <=125
```

As said before, the data exchange feature among more MCP 4 controllers must be activated, during programming step, by one or more configuration directives specifying how many virtual points and/or registers have to be published. These configuration directives are as follows:

```
NETWORK = (Vstart .. Vstop)
NETWORK = (Rstart .. Rstop)
```

Vstart and Vstop means respectively an initial and a final virtual point; any value chosen as Vstart and Vstop will be however forced as multiple of 16 by the compiler of MCP IDE; for instance, choosing v3..v9, the compiler will force v1..v16.

Rstart and Rstop means respectively an initial and a final register; these two values can be set as desired, but remembering that the total number of Words that can be published (virtual points and registers) must be less or equal to 125 as said before.

Each MCP 4 belonging to the network will write in its memory the information published by the other MCP 4 controllers; each Word will be stored in the same position from which it has been originated, therefore the content of register R50 of a MCP 4, for instance, will be stored as R50 by all other MCP 4 controllers. For this reason, of course, the Words published by each MCP 4 must be different from one to the others; in other words, it is mandatory to avoid superimposition of the Words published by the controllers belonging to the same network.

It is also possible to publish non contiguous blocks of virtual points and registers, specifying more **NETWORK** directives, up to a maximum of 8 (as total of V-Words and R-Words). For instance, the following directive may be enclosed in the same MCP 4:

```
NETWORK = (V1 .. V16)
NETWORK = (V513 .. V576)
NETWORK = (V1025 .. V1056)
NETWORK = (R0 .. R8)
NETWORK = (R33 .. R37)
NETWORK = (R50 .. R52)
NETWORK = (R100 .. R100)
NETWORK = (R251 .. R255)
```

To publish only one register, simply specify the same value for Rstart and Rstop (see R100 in the previous example). Each MCP 4 acquires the information published by the other components of the same network even if it does not contain any **NETWORK** directive; for instance, if only one MCP 4 has to send information to the other components of the networks, but not vice-versa, then the **NETWORK** directive may be activated only for the "master" MCP 4 controller.

#### Remember:

- if a **NETWORK** directive has been inserted in a MCP 4, then also an **ADDRESS** directive must be insrted too and this last one must be placed **before** any **NETWORK** directive
- the Words published by a MCP 4 must be different from one to the other in order to avoid superimposition
- > up to 8 **NETWORK** directive can be enabled in each MCP 4 in the network
- ➤ Each MCP 4 acquires the information published by the other components of the same network even if it does not contain any **NETWORK** directive
- the data exchange mechanism here described also applies between **Euntritu** MCP 4 controllers and **Domino** DFCP controller, allowing interactions between the two systems

#### Example:

Suppose to have installed 2 MCP 4; also suppose to have connected, to each one of them, 1 MOD8I/A, 1 MOD8R, both with address 1, 1 MOANI and 1 MOANU, both with address 2. Suppose that the application requires to control the outputs of a bus by the input of the other one and vice-versa..

The programs to be written in the two MCP 4 controllers are:

```
// Program for MCP-4 1
     ADDRESS = (1)
                             // Address of first MCP
     NETWORK = (V1..V16)
                             // Send 16 virtual points to the other MCP
     NETWORK = (R0..R0)
                             // Send 1 register to the other MCP
     V1 = I1.1
                             // Copy the local inputs to first 8 virtual points
     V2 = I1.2
     v_3 = I1.3
     V4 = I1.4
      V5 = I1.5
     V6 = I1.6
     v7 = I1.7
     v8 = I1.8
     01.1 = V17
                             // Copy the received virtual points to the outputs
     01.2 = V18
     01.3 = v19
     01.4 = V20
     01.5 = V21
     01.6 = V22
     01.7 = V23
     01.8 = V24
      R0 = AI2
                             // Copy the analog input to first register
     AO2 = R1
                             // Copy the second register to analog output
// Program for MCP-4 2
     ADDRESS = (2)
                             // Address of second MCP
     NETWORK = (V17..V32)
                             // Send 16 virtual points to the other MCP
     NETWORK = (R1..R1)
                             // Send 1 register to the other MCP
     V17 = I1.1
                             // Copy the local inputs to the virtual points to be sent
     V18 = I1.2
```

```
V19 = I1.3
v20 = I1.4
V21 = I1.5
V22 = I1.6
V23 = I1.7
V24 = I1.8
01.1 = V1
                        // Copy the received virtual points to the outputs
01.2 = V2
01.3 = v3
01.4 = V4
01.5 = V5
01.6 = V6
01.7 = v7
01.8 = V8
R1 = AI2
                        // Copy the analog input to second register
AO2 = R0
                        // Copy the first register to analog output
```

In practice, the status of inputs  $\mathtt{I1.1..I1.8}$  of the module connected to the 1st MCP 4 will be copied to  $\mathtt{V1..V8}$  of the same MCP 4 and published on the networks. The 2nd MCP 4 receives the status of these virtual points and it stores them in the same position  $\mathtt{V1..V8}$ , thus transferring the status to output module  $\mathtt{O1}$  connected on its bus. The same thing happens in the reverse way through the virtual points  $\mathtt{V17..V24}$ ; the same mechanism also applies to the registers.

## 2.1.12- Number of nodes in a MCP 4 network

In a network made as described in the previous paragraph, up to 32 MCP 4 may be installed, each one publishing its data in order to make available them to the other components of the network. Since only one MCP 4 at a time can access the RS485 communication line (COM2), being this of serial type, then the publication of the information by all the components (or nodes) of the network needs a sure time.

Due to the particular management of the mechanism to access to the network, this time can be optimized instructing each MCP 4 about how many are the participants to the same network; too do this, the following directive has to be used:

```
NODESNUM = ( num )
```

where num is the number of nodes and must be in the range 1 to 32.

The time required by all the nodes to publish their information, in the worst case of 125 Words to be published, at 115.2 Kbaud, ranges from a minimum of 80 milliseconds, in the case of 2 MCP 4, to a maximum of 1 second in the case of 32 MCP 4.

If the number of nodes has not been specified by the **NODESNUM** directive, this parameter will be set to 32 by default; in this case the network will work anyway but, if for instance the network is made by 2 MCP 4, the time needed for a full cycle will result increased from 80 milliseconds to 340 milliseconds (at 115.2 Kbaud and in the worst case of 125 Words to be published).

The **NODESNUM** directive is thus optional, but it is useful to drastically reduce the time needed to exchange data among MCP 4 controllers when the number of nodes is less than the allowed maximum value.

#### 2.1.13- Scheduler

The Scheduler allows to control a digital output point (<u>exclusively virtual point</u>) as function of the current day and time. MCP 4 includes a timekeeper circuit with back-up battery to avoid the date and time loss when disconnecting the main power supply. The transition from standard to daylight saving time is made automatically by MCP 4.

MCP 4 includes a complete weekly Scheduler: it allows to specify, for each day of the week, in which time slots the specified output must be activated and which are not.

Such programming is repeated identical for all the weeks of the year. The virtual point controlled by the Scheduler must then eventually reported to the desired physical outputs, in combination with other points if required.

The Scheduler integrated in MCP 4 allows the control of 16 different points ("zones") each one with 8 time slots (8 ON-OFF intervals) for each day of the week. The resolution of the Scheduler is 1 minute.

The Scheduler will be activated by the following directive:

```
SCHEDULER n ( Vx )
```

#### where:

n is the Scheduler number ("zone") and it must be in the range 1 to 16

Rel.: 1.2 October 2018

vx is the controlled virtual point

I the points to be controlled are more than one, more directives must be added as in the following example.

```
SCHEDULER 1 ( V100 )
SCHEDULER 2 ( V101 )
SCHEDULER 3 ( V102 )
```

Unlike CLOCK equation which will be described later, where the specified times are set in the user program and then the change these ones requires reprogramming of MCP 4, the Scheduler here described allows easy setting from any supervision program or through the WEB server (optional) integrated in MCP 4. For details on entering and modification of schedules, refer to the specific documentation.

The following figure shows an example of a page that can be developed for the management of the Scheduler.

## 2.2- Event triggered Equations

## 2.2.1- Logic equations

```
Operators: & (AND), | (OR), ! (NOT), ^ (XOR)
(XOR is evaluated by the compiler as follows: A ^ B = !A & B | A & !B)
010.3 = I1.1
02.5 = (I1.1 \mid I1.2)
V6 = (I4.3 \mid I8.2) & V4
01.6 = V100 & I1.7
01.6 = !I1.3 & I1.7
01.1 = I2.1 & (I4.3 | I2.4)
08.1 = V7 ^ 143.2
```

## 2.2.2- SET – RESET equations

```
Operators:
       s
               SET on the edge
               SET priority on the edge
       SP
       SL
               SET on the level
               SET priority and on the level
       SPL
               RESET on the edge
               RESET priority on the edge
       RP
       RL
               RESET on the level
               RESET priority on the level
       RPL
01.1 = SI1.1 \& RI1.2
                                     Set/Reset edge triggered.
01.1 = SI1.1 \& RI1.2
                                     Set/Reset edge triggered
01.1 = SI1.1 \& RLI1.2
                                     Reset on the level: out is locked OFF if I1.2 is activated.
                                     Set/Reset on the level, but out is locked ON if I1.1 is activated (since
01.1 = SPLI1.1 & RLI1.2
                                     it is specified to be a priority command).
01.5 = I2.3 \& RI2.1 \& SI4.6
                                     I2.3 is a consent.
01.1 = (SI1.1 \mid SI1.2) \& RI1.3
                                            Parenthesis use: out goes ON activating I1.1 or I1.2.
01.1 = SI1.1 \& RI1.2 \& RI1.3
                                             Out goes OFF activating I1.2 or I1.3.
                                             Out goes ON activating BOTH I1.1 and I1.2
01.1 = SLI1.1 \& SLI1.2 \& RI1.3
```

## 2.2.3- TOGGLE equations

#### Operators:

```
TOGGLE on the edge
Т
s
       SET on the edge
SP
       SET priority on the edge
       SET on the level
SL
       SET priority and on the level
SPL
       RESET on the edge
R
       RESET priority on the edge
RP
       RESET on the level
RT.
RPL
       RESET priority on the level
```

Terms must be linked by OR operators; no "free" input can be used.

```
Out toggles at every OFF-ON variation of I6.1 or V6.

O1.1 = T!I6.1 Out toggles at the variation ON-OFF of the input.

V100 = TV1 | SV2 | RV3 Set and Reset on the edge.

V100 = TV1 | SV2 | RLV3 Out is locked OFF until V3 is activated (being on the level).

O1.1 = TI1.1 | TI1.2 | SI1.3 | SI1.4 | RI1.5 | RI1.6 More command inputs.
```

## 2.2.4- COUNTER Equations

Counter equation controls a digital output as function of the comparison between the counter value and a threshold. 1024 counters can be defined. Each counter can be controlled by real or virtual inputs, each one with its own specific function:

- 1. one or more inputs for forward or backward counting (s (k))
- 2. one or more inputs for the zeroing or to load the counter with a defined value (P(z), PP(z), PL(z), PPL(z))
- 3. one or more inputs to stop the counting (H, HP)

The counter, depending on the variations at its inputs, will be updated and then compared to the threshold value, in order to control the output. Allowed operators are:

```
< lower than
<= lower or equal to
== equal to
!= not equal to
> greater than
>= greater or equal to
```

#### Control operators:

| S (k)  | Sum k to counter on the edge (k range: -32768 to 32767)            |
|--------|--|
| P(z)   | Preset counter to z on the edge (z range: 0 to 65535)              |
| PP(z)  | Priority Preset counter to z on the edge (z range: 0 to 65535)     |
| PL(z)  | Preset counter to z on the level (z range: 0 to 65535)             |
| PPL(z) | Priority Preset counter to z on the level (z range: 0 to 65535)    |
| Н      | Lock the counter to the current value on the level (Halt)          |
| HP     | Priority Lock the counter to the current value on the level (Halt) |

All counters of MCP4 are in 16-bit format, thus the content of each counter is in the range 0 to 65535.

For the counter function, the following options can be also specified:

- > AUTORESET/AUTORELOAD
- > MIN
- > MAX
- > Cn,R copy the counter value to a register (with same identifier)
- Variable parameters

The syntax allowing to specify these options is the following (vx may be any allowed point):

$$Vx = Cy/R > 30$$
, AR, MIN, MAX ......

#### where:

- R means that the counter value is continuously copied in a register (with the same identifier)
- AR is the (optional) value for the autoreset and the autoreload, in order to make possible the automatic zeroing and the automatic loading of the counter: when the forward counting exceeds the value AR, then the counter will be automatically zeroed, while when the backward counting decrease below the value 0, then the counter will be automatically reloaded with the value AR. This value can be also the content of a register (see the examples in the following). Note: if the autoreset/autoreload value has not been specified, then the counting will be stopped to 0 (when down counting) and at the maximum allowed value (when up counting), thus avoiding the underflow or the overflow of the counter.
- MIN is the minimum value that can be assumed by the counter; the default value is 0
- MAX is the maximum value that can be assumed by the counter; the default value is 65535

The values for the threshold, autoreset, minimum, maximum, step and preset can be also the content of registers (see the examples in the following).

If one of the options **AR**, **MIN** and **MAX** has been omitted, the default value will be assumed. The described options must be however separated by commas as in the following examples.

#### Examples:

| V1 = C0>300 S(2)I1.1 & S(-1)I1.2                     | Up counting step 2, Down counting step 1, V1 goes ON when counter is greater than 300.   |
|--|--|
| V1 = C0>30,50 S(1)I1.1 & S(-1)I1.2                   | Autoreset/Autoreload: when counter exceeds 50, it is reset to zero; when the counter goes below zero, it is reloaded to 50.    |
| V1 = C0>30, ,5,50 S(1)I1.1 & S(-1)I1.2               | MIN and MAX: the up counting is stopped to 50 and the down counting is stopped to 5.   |
| V1 = C0>3,5,1 S(1)I1.1 & S(-1)I1.2                   | Autoreset/Autoreload and MIN: when counter exceeds 5, it is reloaded to 1; when the counter goes below 1, it is reloaded to 5. |
| V15 = C10,R > 100 S(1)I1.1 & S(-1)I1.2 \ & PL(0)I1.3 | Copy Counter to Reg: the value of C10 is copied to register R10.   |
| V10 = C1 > R0,R1,R2,R3 S(R4)I1.1 \ & P(R4)I1.3       | Variable parameters.   |

## 2.2.5- THRESHOLD Equations

Threshold equation controls a digital output as function of the comparison between an analog value (input module or register) and a Threshold and an Hysteresis. Allowed comparison operators:

- < lower than
- <= lower or equal to
- == equal to
- != not equal to
- > greater than
- >= greater or equal to

#### Options:

- Hysteresis
- Variable parameters

The Hysteresis has a different meaning depending on the comparison operator:

```
OUT goes ON when AI<T and OUT goes OFF when AI>= (T + H)
```

- OUT goes ON when AI<=T and OUT goes OFF when AI>(T + H)
- == OUT goes ON when AI==T and OUT goes OFF when AI>(T + H) or when AI<(T H)
- != OUT goes OFF when AI==T and OUT goes ON when AI>(T + H) or when AI<(T H). This behavior is complementary to the previous case
- > OUT goes ON when AI>T and OUT goes OFF when AI<=(T H)
- >= OUT goes ON when AI>=T and OUT goes OFF when AI<(Т н)

Threshold and Hysteresis must be in the range 0 to 65535. Other allowable operators: AND (&) and OR (|).

#### Examples:

```
O1.1 = AI1 >= 240,2

V2 = AI1 == 40 | AI2 == 30

V2 = AI1 == 40,5

O1.4 = AI1 < 128 & AI1 > 30

O1.5 = AI1 < 600 & R50 >= 30

O1.1 = AI1 > R51,R52 & AI1 < 1000,5
```

## 2.2.6- TIMER Equations

Timer equation controls a digital output as function of two delay times. 512 timers can be defined. The timer resolution is 0.1s and time range is 0 to 6553.5s (1h:49'). The times specified in the timer equation are intended in second multiplied by 10 ( $\tau$ e=100 means 10 seconds).

The input starting the timer is the "trigger" input and it always works on the edge.

#### Keyword:

TIMER Standard timer

TIMERP Non re-triggerable Pulse timer (monostable)
TIMERPR Re-triggerable Pulse timer (monostable)

#### E4ended control operators:

H Lock the timer to the current value on the level (Halt)

- **z** Zero, force the expiring of the current timer value (if running) on the edge
- **ZL** Zero, force the expiring of the current timer value on the level

**Note:** if the Zero on the level command is activated, the trigger status is transferred to the output without delays. The priority sequence for the timer controls is fixed to Halt, Zero and Trigger.

#### Options:

Variable parameters

O1.1 = TIMER(I2.5, 30, 10) 3s delay from I2.5 activation to the out activation; 1s delay from I2.5 deactivation to out deactivation.

V23 = TIMER (!I1.1, 0, 23) Out is complemented in respect to the trigger input.

01.1 = TIMER(I2.5 & HI5.1 & ZI5.2, 90, 50)

Trigger, Halt and Zero: I5.1 halts the timer, I5.2 forces the expiring of the currently running time; if the timer is in stand-by, Halt and Zero controls have not any effect.

O1.1 = TIMERP(I1.1, 0, 20) 2s pulse at the activation of the trigger input; no action at the deactivation of the input.

**01.1** = **TIMERP**(**I1.1**, **10**, **20**) 2s pulse delayed 1s from the activation of the trigger input.

**01.1** = **TIMERPR** (**11.1**, 0, 20) Re-triggerable 2s pulse (computed from last activation of the trigger.

O1.1 = TIMERPR(I1.1, 10, 20) Re-triggerable 2s pulse delayed 1s from the first activation of the trigger input.

O1.1 = TIMER(I1.1, R47, R48) Variable parameters.

## 2.2.7- Equations for mathematical and logic calculation

Allowed MATH and LOGIC operators:

| MATH   |          | LOGIC  |          |
|--------|----------|--------|----------|
| Symbol | Function | Symbol | Function |
| +      | Sum      | &      | AND      |
| _      | Subtract | I      | OR       |
| *      | Multiply | ^      | XOR      |
| /      | divide   | P()    | Preset   |

#### Preset options:

- P Preset on the edge: load the specified value at the edge of the control input
- Preset on the level: load the specified value and lock the result to that value

#### Notes:

- there is no priority between logical and algebraic operators: the equation is calculated sequentially from left to right; brackets are not allowed
- the Preset on level always takes priority over calculation of the equation and over Preset on edge
- if in the same equation more Presets on level are activated, priority is given to the leftmost one
- when a Preset on level is activated, the result of the equation is frozen to the value determined by that same Preset; if instead the Preset is on the edge, the result of the equation will be the value established by that same Preset until no further changes occur to other terms inside the equation
- each terms involved in a calculation equation is 16-bit number; the partial results are evaluated as 32-bit number, but the final result will be truncated to the less significant 16 bits

#### Examples:

```
A01:1 = AI1:4 + 128
R12 = AI1:4 + 12 & 0x00F0 + R1 & P(30)I23.5
R54 = R52 / R53 + R54 * 2
```

A mathematical equation can also be made by one or more Preset terms only; this is useful to load a value in a register or to an output at the activation (or de-activation) of a control input:

```
R0 = P(1527)V1

R1 = P(0x1AB7)I1.8 \& P(0)!I1.8

A023:2 = P(12000)V148 \& P(0b11000011)I12.1 \& PL(0)!I32.7
```

**Exclusively for real outputs** (thus registers, counters etc. are excluded), **it is possible to define multiple Presets activated by the same digital point**; in this case, at the activation of the common digital point, the values defined by the Preset will be sent sequentially to the output, in the order in which they have been entered into the equation (from left to right). The following examples show some possibilities.

```
When V1 goes ON, the values 10, 20 and 30 will be sequentially sent to the output: AO1:1 = P(10)V1 & P(20)V1 & P(30)V1
```

When **v1** goes ON, the values 10 and 20 and 30 will be sequentially sent to the output; when **v2** goes ON, the values 30 and 40 will be sequentially sent to the output:

```
AO1:1 = PL(10)V1 & P(20)V1 & P(30)V2 & P(40)V2
```

When v1 goes ON, only the value 20 will be sent to the output, because it is a Preset on level:

```
AO1:1 = P(10)V1 & PL(20)V1 & P(30)V1
```

When **v1** goes ON, only the value 10 will be sent to the output, because it is the Preset on level placed on the leftmost side in the equation:

```
AO1:1 = PL(10)V1 & PL(20)V1 & P(30)V1
```

## 2.2.8- Equations for binary code generation

Rel.: 1.2 October 2018

Keyword:

SENDn(Tr) Send the specified code to output n at the activation of the related input (or deactivation if complemented), with refresh time Tr seconds (when more inputs are activated)

SENDRn (Tr) Send the specified code to register Rn at the activation of the related input (or deactivation if complemented), with refresh time Tr seconds (when more inputs are activated)

The sent code (Bx) must be in the range 0 to 255. If the refresh time has been omitted, then it will be set to 2 seconds. The refresh time must be in the range 1 to 254 seconds; it is possible to disable the refresh by specifying the value 255. In this case the sent code will be always that related to last change of one among the inputs listed in the SEND block.

The input points causing the sending of the related binary code may be real and virtual ones; they can be also complemented.

Up to 16 independent SEND block can be defined.

```
SEND4 (5) = ( I1.1, B001,
            I1.2, B002,
                             ١
            V354, B003,
                             ١
            !I4.7, B006,
            !V450, B129
SENDR123(2) = (15.8,
                      B001,
               V100,
                      B002,
               V101, B003,
              !V470, B004,
              !V480,
                     B005
)
```

Note: commas are mandatory symbols.

## 2.2.9- Equations for recording status changes (EVENT)

This function allows to store, in chronological order, the status change of the real input points and of the virtual points that have been specified in the EVENT block. Each status change will be stored together to:

```
Day/Month Hour:Minutes:Seconds
```

The EVENT function allows to specify if MCP 4 has to store the OFF-ON or the ON-OFF status change or both. The EVENT function will also automatically register the so called "system events", that are the failure and the restoring of any module and of the bus; the doubled address events will be automatically registered too. Up to 2048 events can be stored in the RAM.

The section of the RAM where these events are stored has the battery back-up feature, therefore the events remain stored even if the main supply voltage fails (at least until the battery does not reach the minimum retaining voltage of the memory).

Keyword:

| EVENT  | Create the event list (fixed buffer): when the buffer is full, it does not accept any other |
|--------|---|
|        | event (in this way the list contains the first 2048 events from the last cleaning of the    |
|        | buffer)   |
| EVENTC | Create the event list (circular buffer): when the buffer is full, it overwrites the old     |
|        | events (in this way the list contains the last 2048 events)                                 |

Rel.: 1.2 October 2018

No more than 1 EVENT block can be declared in the same MCP 4 module. If the buffer is full (case EVENT) or the old events have been overwritten (case EVENTC), then the virtual point **V2008** will be activated to report this occurrence.

```
EVENTC = ( \ Inizio blocco, il buffer è circolare
V1, ON, \ Evento 1, alla transizione 0-1 di V1
V2, OFF, \ Evento 2, alla transizione 1-0 di V2
I3.7, ON, OFF \ Evento 3, ad entrambe le transizioni 0-1 e 1-0 di I3.7
```

Note: commas are mandatory symbols.

## 2.2.10- Equations for recording value changes (LOG)

This function allows to store, in chronological order, the change of the value returned by input modules or registers that have been specified in the LOG block. Change in the value means exclusively a change from any value to another one, on condition that the new value is not zero, unless this has not been expressly declared; in other words, any change from zero to any other value, or from any value to another one (but not zero) will be registered, while a change from any value to zero will not be registered, unless not expressly declared in the LOG block. For instance:

- 1. a change from 0 to 287 will be registered
- 2. a change from 287 to 584 will be registered
- 3. a change from 584 to 321 will be registered
- 4. a change from 321 to 0 will NOT be registered, unless not expressly declared

This function is useful, for instance, to record the codes of the transponders controlling an access to a building. In the LOG block can be specified both real input addresses (specifying the channel if any) and registers. Each value change will be stored together to:

#### Day/Month Hours:Minutes:Seconds

Up to 1024 16-bit values (or codes) can be stored in the RAM of MCP 4; since the section of the RAM where these events are recorded has the battery back-up feature, the values remain stored even if the main supply voltage fails (at least until the battery does not reach the minimum retaining voltage of the memory).

#### Keyword:

| LOG  | Create the value list (fixed buffer): when the buffer is full, it does not accept any other |
|------|---|
|      | value (in this way the list contains the first 1024 value from the last cleaning of the     |
|      | buffer)   |
| LOGC | Create the value list (circular buffer): when the buffer is full, it overwrites the old     |

values (in this way the list contains the last 1024 values)

Option:

**ZERO** Declare that, for the related input or register, also changes from any value to zero

has to be recorded

Rel.: 1.2 October 2018

**No more than 1** LOG block can be declared in the same MCP 4 module. If the buffer is full (case LOG) or the old events have been overwritten (case LOGC), then the virtual point **V2009** will be activated to report this occurrence.

Note: commas are mandatory symbols.

## 2.2.11- Management of the external counter modules (ModCNT)

The counter module (code number ModCNT) is an external module (connected to the CDITITITO bus) which counts the pulses applied to its inputs; it stores the total amount of the counting in its non volatile memory. The management of this module by MCP 4 needs a special function, specified by an equation very similar to that one for the management of the internal counters. Each ModCNT counter module features 4 counting channels, thus the equation must specify the channel to be managed.

MCP 4, through a threshold equation, can continuously read the content of each external counter and it can compare it to the threshold value; the result of the comparison controls a digital (real or virtual) output. Allowed comparison operators are:

- < lower than
- <= lower or equal to
- == equal to
- != not equal to
- > greater than
- >= greater or equal to

It is also possible to specify a real or virtual input which, when activated, reset to the value 0 the counter specified in the equation; this is however an optional input and must be linked by the operator "&". The threshold value also can be the content of a register.

#### Examples:

```
O1.1 = AI10:2 >= 100 & ZI1.1 The output is controlled by channel 2 of ModCNT module, addressed 10; the output will be activated if the counting is greater or equal to 100. The input I1.1, when activated, will reset the counter to 0.

V10 = AI10:4 > R0

The virtual point V10 will be activated if the counting of the channel 4 of ModCNT module addressed 10 is greate than the content of register R0.
```

## 2.2.12- Management of DALI module (ModDALI)

This equation allows to simplify the management of ModDALI module, especially in systems where the automatic brightness regulation has to be implemented. The syntax of DALI equation is the following:

```
AOUT = DALI (Code, AIN(offset))
```

where:

**AOUT** output (address:channel of ModDALI to be managed) or register where the result of equation

will be sent

Code DALI command type (broadcast, single ballast or group)

analog input whose value must be transferred (typically address:channel of ModLC sensor)

or register containing the value to be transferred

offset value or register containing a value in the range -100 to 100; this value will be algebraically

added to **AIN**; this is useful, for instance, when the brightness regulation from a unique sensor must be differentiated between rows of lamps depending on the distance from

Rel.: 1.2 October 2018

windows

At every change of one of the **AIN** values inside the **DALI** block, the related value will be transferred to the specified channel of ModDALI module and, by this one, to all ballasts, or to a single ballast, or to a group depending on the value of **Code**.

The allowed Code, therefore the DALI destinations, are the following:

```
Code = 0xXXdirect declaration of the code in hexadecimal format; for instance 0x81 means,<br/>according to DALI specifications, that AIN must be sent to group 1Code = B1..B32equivalent to 0x01..0x20, for commands to single ballastCode = G1..G16equivalent to 0x81..0x90, for group commandsCode = ALLequivalent to 0x00, for broadcast commands
```

#### Example:

These commands will be sent, in this example, to channel 2 only of DALI module addressed 1 (AO1:2).

Note: commas are mandatory symbols.

## 2.3- Time triggered Equations

## 2.3.1- Scheduler Equations

Scheduler equation controls a digital output as function of specified ON/OFF time or date. MCP 4 includes a timekeeper with back-up battery to avoid the date and time loss when disconnecting the main power supply. The transition from standard to daylight saving time is made automatically by MCP 4, therefore no intervention of the user is required.

The times specified in the scheduler equations can be daily or weekly times; the scheduled dates can be yearly or absolute dates.

#### Keyword:

CLOCK controls the output as function of current time controls the output as function of the current date

#### Options:

- ➤ Variable daily scheduling times specified in a register (Rx) or in a Word (@WORD x) containing a number in the range 0 to 1439, corresponding to the number of minutes of the day starting from 0:00 (1439 = 23:59); the formula giving the number related to time hh:mm is the following: (hh x 60) + mm
- ➤ Variable weekly scheduling times specified in a register (Rx) or in a Word (@WORD x) containing a number in the range 0 to 10079, corresponding to the number of minutes of the week starting from 0:00 of Monday (10079 = 23:59 of Sunday); the formula giving the number related to time DW:hh:mm, assuming for the days of the week (DW) MON=0...SUN=6, is the following: (DW x 1440) + (hh x 60) + mm
- ➤ Variable yearly dates specified in a register (Rx) or in a Word (@WORD x) containing a number in the range 1 to 372 corresponding to the day of the year starting from January 1 (372 = December 31); the formula giving the number related to the day DD (1÷31) of month MM (1÷12) is the following: (MM –1) x 31 + DD
- Variable absolute dates specified in a register (Rx) or in a Word (@WORD x) containing a number in the range 1 to 37200 corresponding to the day of the century starting from January 1 00 (37200 = December 31, 99); the formula giving the number related to the day DD (1÷31) of month MM (1÷12) of year YY (0÷99) is the following: (372 x YY) + (MM –1) x 31 + DD

#### Notes:

- the argument x of the notation @WORD x may be in the range 0 to 65535; this is true, unless otherwise specified, for the CLOCK and DATE equations only
- the timing 24:00 is not allowed; use instead the timing 00:00, taking attention that it is the morning of the specified day.

| O1.1 = CLOCK(8:15, 17:30)                                       | Out is ON everyday from 8:15 to 17:30 (daily scheduling).                                   |
|---|---|
| V3 = CLOCK (MON:8:00, FRI:20:00)                                | Out is on from Monday 8:00 to Friday 20:00 (weekly scheduling).                             |
| O3.2 = DATE(31/07, 02/09)                                       | Out is ON from July 31 to September 9 (yearly scheduling).                                  |
| O3.2 = DATE(31/07/05, 02/09/05)                                 | Out is ON from July 31,2005 to September 9, 2005 (absolute scheduling).                     |
| V4 = CLOCK(TUE:8:00, TUE:12:00)   \ CLOCK(THU:14:30, SAT:00:00) | Out is ON the Tuesday 8:00 to 12:00 and it is also ON from Thursday 14:30 to Saturday 0:00. |

| V6 = DATE(12/01/06, 15/01/06)   \ DATE(20/01/06, 22/01/06) | Out is ON from 12/01/06 to 15/01/06 and from 20/01/06 to 22/01/06.   |
|--|--|
| V8 = DATE(12/01/06, 15/01/06) & \ CLOCK(10:00, 17:00)      | Out is ON from 10:00 to 17:00 but only in the specified days.  |
| O1.1 = CLOCK(XX:R0, XX:R1)                                 | Daily switching ON at time specified by R0 and daily switching OFF at the time specified by R1. For example, if R0=675 and R1=1280, then out will be ON everyday from 11:15 to 21:20.                                |
| O1.1 = CLOCK (XX:@WORD32770, XX:@WORD3277                  | <ol> <li>As the previous equation, but the times are<br/>specified by the shown Words.</li> </ol>  |
| 01.1 = CLOCK(R0, R1)                                       | Weekly switching ON at time specified by R0 and weekly switching OFF at time specified by R1. For example, if R0=675 and R1= 6780, then out will be ON every week from Monday 11:15 to Friday 17:00.                 |
| O1.1 = CLOCK(@WORD32770, @WORD32771)                       | As the previous equation, but time are specified by the shown Words.   |
| O1.1 = DATE (R0/XX, R1/XX)                                 | Switching ON every year at the date specified by register R0 and switching OFF every year at the date specified by R1. For example, if R0=48 and R1=82, then out will be ON every year from February 17 to March 20. |
| O1.1 = DATE(@WORD32770/XX, @WORD32771/XX                   | As the previous equation, but the dates are specified by the shown Words.  |
| O3.2 = DATE(R3, R4)  | Switching ON at the absolute date specified by register R3 and switching OFF at the date specified by R4. If R3=675 e R4=6780, the output will be ON from October 24,01 to March 22,18.                              |
| O3.2 = DATE(@WORD32776, @WORD32777)                        | As the previous equation, but the absolute dates are specified by the shown Words.   |

#### 2.4- Macro

A MACRO is a sequence of equations that can be inserted in more points of MCP 4 source program by using a single call to the MACRO itself. The MACRO must first be defined in the Macros TAB of MCP IDE tool software, then it can be referred to in the program as many times as needed (in the Equations TAB of MCP IDE).

Each MACRO can have several arguments (parameters); the number of arguments must be the same in the MACRO definition and in each call. The compiler will link the arguments in the call to the arguments in the MACRO definition, in the same order they were written. It is important to understand that:

- the MACRO directive only applies to standard MCP 4 equations, it cannot be applied to SCRIPTs
- the MACRO directive is an utility of the compiler, it is not a feature of MCP 4; in other words, the
  compiler "explodes" each call to a MACRO into the equations specified in the definition of the
  same MACRO, simply replacing each argument in the definition with the related argument passed
  by the call

Up to 256 MACROs, each one with up to 32 arguments, can be defined in a MCP 4 program.

The definition of a MACRO is opened by the keyword MACRO followed by the name chosen for the MACRO and, inside round brackets, the arguments to be passed to. The definition of a MACRO is closed by the keyword ENDMACRO.

The required equations have to included inside this block, taking in account that the arguments in the MACRO definition (that are variable parameters because they change from a call to the other one) cannot have the same names reserved to the parameters or the keywords of MCP 4.

The following example defines a MACRO named DIMMER; this MACRO allow to control a dimmer output (e.g. a MOD2DM module) whose address is OUT; the brightness level is controlled by an UP pushbutton and by a DOWN pushbutton and, to implement the needed equation, a counter CX and a register RX are also used; the argument list is closed by two virtual points VP1 and VP2, needed to realize the wanted function.

The MACRO definition is the following (refer to the technical sheet of MOD2DM module for more details about the meaning of the used equations):

```
MACRO DIMMER (OUT, UP, DOWN, X, VP1, VP2)

VP1 = !(UP | DOWN)

VP2 = CX,R==1 P(129)UP & P(130)DOWN & P(128)VP1

OUT = RX
```

#### **ENDMACRO**

If, for instance, 6 dimmer outputs must be controlled in the plant, with identical operation but with different command inputs, the just defined MACRO can be called 6 times as follows:

```
DIMMER (AO1, I1.1, I1.2, 0, V1 , V2)
DIMMER (AO2, I1.3, I1.4, 1, V3 , V4)
DIMMER (AO3, I1.5, I1.6, 2, V5 , V6)
DIMMER (AO4, I1.7, I1.8, 3, V7 , V8)
DIMMER (AO5, I2.1, I2.2, 4, V9 , V10)
DIMMER (AO6, I2.3, I2.4, 5, V11, V12)
```

As it can be seen, a different argument list is passed at each call. The compiler will "explode" this program in a sequence of equations that is more difficult to be interpreted and to be modified. In other words, the compiler will translate the few program lines in the previous example as follows:

```
V1 = !I1.1 & !I1.2

V2 = C0,R == 1 P(129)I1.1 & P(130)I1.2 & P(128)V1
```

```
AO1 = RO

V3 = !I1.3 & !I1.4

V4 = C1,R == 1 P(129)I1.3 & P(130)I1.4 & P(128)V3

AO2 = R1

V5 = !I1.5 & !I1.6

V6 = C2,R == 1 P(129)I1.5 & P(130)I1.6 & P(128)V5

AO3 = R2

V7 = !I1.7 & !I1.8

V8 = C3,R == 1 P(129)I1.7 & P(130)I1.8 & P(128)V7

AO4 = R3

V9 = !I2.1 & !I2.2

V10 = C4,R == 1 P(129)I2.1 & P(130)I2.2 & P(128)V9

AO5 = R4

V11 = !I2.3 & !I2.4

V12 = C5,R == 1 P(129)I2.3 & P(130)I2.4 & P(128)V11

AO6 = R5
```

Rel.: 1.2 October 2018

This example well clarify how to use the MACRO utility to execute block of repetitive equations, where only some parameters change.

In addition, and this is another great advantage in using the MACRO utility, a required change to the operation of the system will be reduced to the modification of the MACRO definition.

#### 3- SCRIPT

## 3.1- Summary

Scripts allow to implement sections of program that will be executed in sequential mode by MCP 4. Each Script can be started ("triggered") by an event or it can be executed every a well specified time period. Each defined script must be numbered; up to 127 scripts may be defined.

The scripts *must* be used only to execute functions that cannot be realized by the standard equations of MCP 4. The duration of a script must be lower than 500msec, on the contrary MCP 4 will interrupt its execution (and it will set the related virtual point V2004). Therefore, be aware of the loops nested into a script.

| Keyword             | Meaning   |
|---------------------|---|
| SCRIPT              | Enclose the instructions belonging to the script: SCRIPT declares the start and ENDSCRIPT   |
| ENDSCRIPT           | declares the end  |
| TRIGGER             | Specify the event that starts the SCRIPT or the time execution period in seconds  |
| EXIT                | Force the exit from the script  |
| VAR                 | Declare a local variable, therefore not shared with the other scripts   |
| GLOBAL VAR          | Declare a global variable, therefore shared with all other scripts  |
| EXTERN VAR          | The specified variable has been declared as global in another script  |
| &,  , ^, !          | logical operators (no parenthesis are allowed and no more than one operation for each line is allowed)  |
| +, -, *, /, =       | mathematical operators (no parenthesis are allowed and no more than one operation for each line is allowed)   |
| IFTHENELSE<br>ENDIF | Condition. IF and ENDIF enclose the block. An IF must be always closed by an ENDIF  |
| >,>=,==,<,<=,<br>!= | Comparison operators (greater than, greater or equal to, equal to, less than, less or equal to, not equal to)   |
| CARRY               | Bit (flag) whose value is 1 if the result of the previous operation exceeds the value 65535 (overflow) or if the result of the previous operation is negative (underflow) or if a division by 0 occurred; the value of this bit is 0 in all other cases |
| ZERO                | bit (flag) whose value is 1 if the result of the previous operation is zero; the value of this bit is 0 in all other cases  |
| DEFINE              | assign a name to a variable or to a parameter or to a constant  |
| GOTO                | unconditional jump  |
| CALL                | jump to a subroutine or function (which is a section of a script); from a script, it is possible to call a subroutine contained into another script   |
| SUBENDSUB           | Enclose a block of instructions as subroutine or as function; the subroutines that have been declared in a script can be "seen" and used by any other script  |
| RET                 | Exit from a subroutine or function  |
| BIT(x)              | Declare that parameter x of a subroutine or function or the value returned by a function is a bit; the declaration BIT(x) applies to subroutines or functions only  |
| WORD(x)             | Return the number of the Word where the point x is mapped   |
| [ptr]               | Pointer: it returns the content of the Word whose address is the value of the variable inside the square brackets (ptr in this case); in other words, ptr points to the Word address and [ptr] is the content of the "pointed" Word (see examples)      |
| @WORD k             | It returns the content of the Word k, where k is a constant value in the range 0 to 32767   |
| @RAM k              | It returns the content of the two consecutive bytes starting at address is k, where k is a constant value in the range 0 to 65535   |
| SWAP(x)             | exchange the high byte with the low byte of specified Word (x)  |
| RANDOM(0)           | Function that returns a 16-bit random number  |
| BMASK(x)            | Function that returns a 16 bit number having, in its binary format, only one bit set to 1 at the position of (x-1)%16 (that means (x-1) module 16); this function is useful for bit operations  |

Quite all notations belonging to the equation syntax of MCP 4 may be used in the scripts. For instance, the following notations are allowed:

```
IF AI1:2 > 230; THEN.......

AO4 = 197

R54.1 = 1

IF I81.1 == 1; THEN......

O34.7 = 0

V781 = 1

IF V542 == 0; THEN.....
```

Refer to the examples in the following pages for more allowed notations.

#### Notes:

- 1. the writing operations on the outputs and on the registers will be executed as a sequential sequence, in the same order as they appear in the script
- 2. the keywords can be written both in upper and lower case
- 3. more instruction (statements) on the same line must be separated by the symbol ";"
- 4. when writing scripts, use the tab in order to enhance the readability of the script itself (e.g. increase the indent of the instructions in the blocks IF...ENDIF); see example for more details.

## 3.2- Keywords and syntax

## 3.2.1- Using the TRIGGER

The keywords SCRIPT and ENDSCRIPT "enclose" the script. The keyword SCRIPT must be followed by a number in the range 1 to 127.

The keyword TRIGGER specifies the event triggering the execution of the script or every how many time it must be executed.

The events triggering the scripts can be only real inputs (direct or complemented) or virtual points (direct or complemented). It is allowed, in the same MCP 4 program, to have a script triggered by the a real or virtual point and another script triggered by the same but complemented point; in this way it is possible to execute a script at the activation of a point and another script at the de-activation of the same point.

```
The following script (SCRIPT 1) will be executed every 1 second (TRIGGER=1):
SCRIPT 1
       TRIGGER = 1
       .....
ENDSCRIPT
The following script (SCRIPT 2) will be executed at every change OFF to ON of V1:
SCRIPT 2
       TRIGGER = v1
ENDSCRIPT
The following script (SCRIPT 3) will be executed at every change ON to OFF of V1:
SCRIPT 3
       TRIGGER = !v1
       .....
ENDSCRIPT
The following script (SCRIPT 4) will be executed at every change OFF to ON of I2.1:
SCRIPT 4
       TRIGGER = I2.1
       .....
ENDSCRIPT
```

## 3.2.2- VAR, GLOBAL VAR and EXTERN VAR

The scripts allow to use how many variables are required for the execution of the program. The variables used in the scripts must be explicitly declared. Essentially, the variables can be grouped in two classes:

- ➤ Local: these variables will not be shared among the several scripts, therefore two variables having the same name, but declared in two different scripts, will be separately handled; a local variable is created at the input of the script and destroyed at the output of the same script
- Global: these variables are shared among the scripts, and therefore they can be used by all the scripts. A global variable, once created, will be kept also at the exit of a script, therefore each script always will read the last value that has been assigned to the variable itself

The VAR instruction in a script defines a local variable, and the GLOBAL VAR instruction defines a global variable. Since all variables in a script must be declared, the instruction EXTERN VAR informs a script that the variable has been declared in another script.

In the following example, the variable TEMP1 is declared as local, both for script 1 and for script 2, while the variable is shared by both script.

```
script 1
    trigger = 2
    var TEMP1
    global var TEMP2
.....
endscript
script 2
    trigger = 2
    var TEMP1
    extern var TEMP2
......endscript
```

The local variables used by a subroutine must be declared inside the subroutine itself, not in the script containing it; in other words, if a local variable has been declared in a script, the same variable cannot be accessible by a subroutine contained in the same script.

## 3.2.3- Logic and Mathematical operations

The scripts allow to execute the main logic and mathematical operations. The allowed logic and mathematical operators are:

- & AND
- I OR
- ^ EXOR
- ! NOT
- + Sum
- Subtract
- Multiply
- / Divide
- = Equal

No parenthesis are allowed in logic and mathematical operations and no more than one operation for each line is allowed. Keep in mind that the result of the logic and mathematical operations is always a 16-bit integer number. If the result is a negative number, then it will be in the two's complement format.

DUEMMEGI

The following script shows some examples about Logic and mathematical operations.

```
script 1
    trigger = 1
    R0 = R1 + R2
    R0 = R0 + 10
    A01 = R100 / 2
    R50 = R51 & 0b11111111100000000
endscript
```

An operation of the type VAR = VAR [op] K, where VAR is a variable, K is a constant number and [op] is one of the described logic/mathematical operators (= excluded), the optional notation VAR += 10 can be used. For instance R0 = R0 + 10 and R0 += 10 are absolutely equivalent notations.

#### 3.2.4- IF...THEN...ELSE...ENDIF

The IF...THEN...ENDIF block allows to execute, if the specified condition is true, the instructions included between THEN and ENDIF. If the condition is not true, then the execution will jump to ENDIF or to ELSE if this has been specified (ELSE is an optional keyword). If ELSE has been specified, then the instruction included between ELSE and ENDIF will be executed.

Each IF block must be always closed by an ENDIF which is mandatory (on the contrary to ELSE which is optional).

The condition of the block IF...THEN...ENDIF must be specified using the following comparison operators:

```
> Greater than
>= Greater than or equal to
= Equal to
< Less than
```

<= Less than or equal to

!= Not equal to

The following script includes two IF...THEN...ENDIF blocks; note that the first block is written on the same line, therefore the ";" symbol must be used to split the several instructions. The second IF...THEN...ENDIF block, on the contrary, is written on more lines, therefore the ";" symbol is not required.

```
SCRIPT 1
TRIGGER = 1

IF R0>25 THEN; R0=1; ENDIF
IF R0==0 THEN
R1=140
R2=50
V1=1
ENDIF
ENDSCRIPT
```

The following script includes an IF block with ELSE.

```
SCRIPT 1
    TRIGGER = 1
    IF I4.7 = 1 THEN
        O1.1 = I1.1
    ELSE
        O1.1 = 0
    ENDIF
ENDSCRIPT
```

Note, in both examples, how tabulations help to better identify the beginning and the end of the IF blocks. If the argument of the condition is a bit, then the comparison operator can be omitted; for instance the two notations:

```
if R0.1==1 then and if R0.1 then are absolutely equivalent statements.
```

#### 3.2.5- CARRY and ZERO

CARRY and ZERO are two system bits (also called flags) providing information about the result of the just executed mathematical or logic operation.

The CARRY flag value is 1 if the result of the previous operation exceeds the value 65535 (overflow), or if the result of the previous operation is negative (underflow), or if a division by 0 occurred.

The ZERO flag value is 1 if the result of the previous operation is zero. The following SCRIPT shows the use of these flags.

```
script 1
      trigger = 2
      R0 = R1 + R2
                        // somma R1 + R2
      if CARRY then
           R0 = 65535
                        // se risultato >= 65535 allora R0=65535
      endif
      R3 = R4 - R5
                        // differenza R4 - R5
      if CARRY then
                        // se risultato < 0 allora R0=0
           R3 = 0
      endif
      R6 = R7 - R8
                        // differenza R7 - R8
      if ZERO then
            V1 = 1
                        // se risultato = 0 allora V1=1
      else
                        // altrimenti V1=0
            V1 = 0
      endif
endscript
```

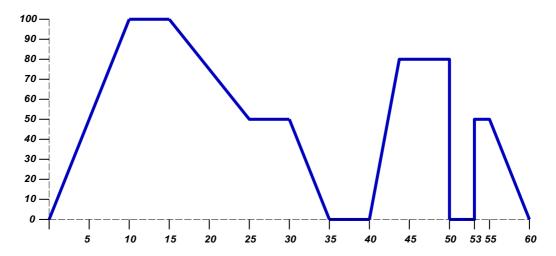

#### 3.2.6- **DEFINE**

The following script use the **define** keyword to assign a mnemonic name to some points, enhancing in this way the readability of the program.

```
SCRIPT 1
      TRIGGER = 1
      define
                  Enable
                              R0.1
      define
                              I1.1
                  Input
      define
                  Lamp
                               01.1
      IF Enable = 1 THEN
            Lamp = Input
      ELSE
            Lamp = 0
      ENDIF
ENDSCRIPT
```

The following script shows how is possible to implement quite complex functions. The following SCRIPT implements a single channel Dynamic Light system, that is a light game obtained by a dimmer output module (e.g. MOD2DM). The dynamic light game shown in the following graph has to be implemented (the percentage of brightness is on the vertical axis and the time, in seconds, on the horizontal axis); after 60 seconds, the cycle will be repeated from the beginning.

The SCRIPT will be executed one time per second. First of all, the script declares one local variable (Step) and 2 parameters (two times A01, the reason of this double definition will be explained in the following). The variable Step represents the amount of seconds elapsed from the beginning of the dynamic light game. At the output from the script, the value of Step will be increased by 1; if the result of this increment is >=60, then Step will be re-initialized to zero.

When the Step value equals one of the moments when the light brightness must be changed, the two instructions RAMP1=K and PERC1=Z will be executed; the effect of this instructions (that are identical to A01=K and A01=Z) is to transfer to the output A01 the specified values, in the same order they were written. The first value to send to output will be the ramp value, the second one will be the wanted percentage. The use of two different definition for the same output (A01) is only to make the script more readable and intuitive.

For the correspondence between the code and the ramp value, see the MOD2DM technical sheet.

```
SCRIPT 1
      TRIGGER=1
      var
            Step
      define RAMP1
                       A01
      define PERC1
                       A01
      IF Step==0 THEN; RAMP1=150; PERC1=100; ENDIF
      IF Step==15 THEN; RAMP1=160; PERC1=50; ENDIF
      IF Step==30 THEN; RAMP1=150; PERC1=0 ; ENDIF
      IF Step==40 THEN; RAMP1=145; PERC1=80; ENDIF
      IF Step==50 THEN; RAMP1=140; PERC1=0 ; ENDIF
      IF Step==53 THEN; RAMP1=140; PERC1=50; ENDIF
      IF Step==55 THEN; RAMP1=150; PERC1=0 ; ENDIF
      Step = Step+1
      IF Step>=60 THEN; Step=0; ENDIF
ENDSCRIPT
```

Rel.: 1.2 October 2018

Of course, other dimmer outputs may be inserted in the same script, in order to realize a multi-channel dynamic light game.

#### 3.2.7- GOTO

The GOTO instruction causes an unconditional jump to the line of the same script identified by a label. The label used to identify the destination of a jump must be followed by ":" symbol and placed on an empty line. The label on the GOTO line, instead, must not be followed by the ":" symbol (see next example).

```
script 1
      trigger = 1
      if R0 == 1 then
            goto ABC
      endif
      if R0 == 2 then
            goto DEF
      endif
      R10 = 0
      exit
ABC:
      R10 = 101
      exit
DEF:
      R10 = 237
      exit
endscript
```

## 3.2.8- SUBROUTINES and FUNCTIONS

A Subroutine or a Function is a sequence of instructions that can be executed many times by one or more scripts. The instructions in a subroutine must be surrounded by SUB and ENSUB keywords. All the subroutines of a program, optionally, may be contained in an single script; in this case, the script containing the subroutine does not need the TRIGGER instruction (but only if the same script contains only subroutines).

The definition of a subroutine automatically causes the declaration of a **global** variable having the same name of the subroutine and that can be used to return a value (typically the result of the function). To "call" a subroutine the CALL instruction can be used, or the function can called in a direct mode. The following rule is always true:

- > Use CALL if the subroutine, after the calling, does not return any value
- > Call directly the function if, after the calling, it must return a value

At every calling of a Subroutine or Function, **one or more parameters can be passed as inputs** (both variables and constants), specifying them inside round brackets. The variable parameters **can be passed as reference or as value**. The difference among the two cases is the following:

- Parameters passed as reference: the Word address of the parameter (input, output, register, etc.) will be copied to the related parameter of the subroutine and it will be used as pointer inside the subroutine itself. In this way, the parameter passed to the subroutine can be both read and modified by the subroutine
- Parameters passed as value: the value of the parameter (input, output, register, constant, etc.) will be copied to the related parameter of the subroutine and it will be used as variable inside the subroutine itself. In this way, the parameter passed to the subroutine can be read but cannot be modified by the subroutine. An edit operation on that parameter inside the subroutine will change the value of the local variable created to receive the parameter but it will not change the parameter passed at the calling

The syntax used to specify what method must be applied to each passed parameter is the following:

```
SUB NAMESUB( PAR1, PAR2, [PAR3], [PAR4]) Where:
```

- > PAR1 and PAR2 are parameters passed as value
- PAR3 and PAR4 are parameters passed as reference, being surrounded by square brackets

To specify that a parameter must be interpreted as reference is thus necessary an enough to surround the related parameter by square brackets in the line defining the subroutine (and only in that line).

Note: parameters of bit type (e.g. V1, O3.2, I4.3, etc.) cannot be passed as reference; these parameters can be passed as value only.

The following two examples show each one a calling to subroutine with parameters:

calling to subroutine to which 3 parameters are passed; there is not a value returned by the subroutine.

The parameter AO1 will be passed as reference, therefore the subroutine can change the value of the parameter itself. RO, on the contrary, will be passed as value, therefore the subroutine cannot change the original value contained in the parameter itself.

Last parameter is a numerical constant value.

function to which 2 parameters are passed and which will return a value copied in R100.

The parameter R11 will be passed as reference, therefore the function can change the value of the parameter itself. R10, on the contrary, will be passed as value, therefore the function cannot change the original value contained in the parameter itself.

#### Notes:

- a Subroutine or a Function, when called by a script other than the script where the function was included, must be placed before the calling itself.
- > if a subroutine uses local variables, these ones must be declared inside the subroutine itself.
- > a Subroutine can call another Subroutine for a max total of 16 nested calls.

Rel.: 1.2 October 2018

For the subroutines and the functions without parameters, the following points must be taken in account:

- 1. if a subroutine or a function does not require input parameters, it **must be however** declared using the parenthesis "()" without the parameters list; for instance; **sub TEMPERATURE()**
- 2. the calls to subroutines or functions without parameters can be written with or without parenthesis; for instance, the following calls are exactly equivalent:

```
R0 = TEMPERATURE()
R0 = TEMPERATURE
call TEMPERATURE()
call TEMPERATURE
```

#### Example:

The following script converts to °C the 4 analog values read from a MODNTC (that are normally expressed as Kelvin degrees multiplied by 10). The result of the conversion is written to register from R0 to R3. A function will be used because the mathematical operations to be executed have to be repeated for each channel. The main script passes to the function the Address:Channel information (as value); the result will be returned in the variable CONVERT. Note that the instruction EXIT closes the script (it is like a GOTO to the ENDSCRIPT instruction).

```
script 1
      trigger = 2
      define NTC1 AI1:1
      define NTC2 AI1:2
      define NTC3 AI1:3
      define NTC4 AI1:4
      R0 = CONVERT (NTC1)
      R1 = CONVERT (NTC2)
      R2 = CONVERT (NTC3)
      R3 = CONVERT (NTC4)
      exit
      sub CONVERT (TEMPER)
            CONVERT = TEMPER - 2730
            CONVERT = CONVERT / 10
      endsub
endscript
```

The same result can be achieved also using the following script, where the destination registers will be passed as reference and therefore the subroutine works directly on them. Prefer however the version of the previous example for its efficiency (for reasons going beyond the matter of this manual).

```
script 1
      trigger = 2
      define NTC1 AI1:1
      define NTC2 AI1:2
      define NTC3 AI1:3
      define NTC4 AI1:4
      call CONVERT (RO, NTC1)
      call CONVERT(R1, NTC2)
      call CONVERT(R2, NTC3)
      call CONVERT(R3, NTC4)
      exit
      sub CONVERT([REG], TEMPER)
            TEMPER = TEMPER - 2730
            REG = TEMPER / 10
      endsub
endscript
```

## Example:

The following script shows how the **RET instruction** allows to exit from the subroutine (it is like a GOTO to the instruction ENDSUB). This script converts to Celsius degrees the analog value read from a MODNTC and it places the result in the register R1; in addition it switches ON the output O1.1 if the result is in the range 18 to 23 degrees, otherwise it switches OFF the output.

```
script 1
      trigger = 5
      define NTC1 AI100:1
      R1 = CONVERT(NTC1)
      exit
      sub CONVERT (TEMPER)
            CONVERT = TEMPER - 2730
            CONVERT = CONVERT / 10
            if CONVERT >= 23 then
                  01.1 = 0
                  ret
            endif
            if CONVERT <= 18 then
                  01.1 = 0
                  ret
            endif
            01.1 = 1
      endsub
endscript
```

## 3.2.9-BIT(x)

The parameter passed to a subroutine or function and the optional returned value are, for default, integer 16-bit numbers. If a bit must be passed to a function or if the returned parameter must be a bit, then it must be explicitly declared by the BIT(x) keyword.

BIT(x) declares that parameter x of a subroutine or function, or the returned value, is a bit; the declaration BIT(x) must be used in subroutines or functions only.

The declaration BIT(X) must be placed in the subroutine declaration ONLY.

Rel.: 1.2 October 2018

The following script uses a function having as input parameters a value (REG) and a bit (ENABLE), that therefore has been specified by the declaration BIT(ENABLE); the function returns a value (RSET).

```
script 1
      TRIGGER = 5
      var RTEMP
      R82 = RSET(R50, V1)
      R83 = RSET(R51, V2)
      R84 = RSET(R52, V3)
      R85 = RSET(R53, V4)
      exit
      sub RSET( REG, BIT(ENABLE) )
            if ENABLE == 1 then
                  RSET = REG / 2
                  RSET = RSET + 128
            else
                  RSET = 0
            endif
      endsub
```

#### endscript

The following script uses a function having as input parameters two values (REG1 and REG2); the function returns a bit (TEST) that therefore has been specified by the declaration BIT(TEST) ( REG1, REG2).

```
script 2
      TRIGGER = 5
      var RTEMP
      RTEMP.1 = TEST(R0, R1)
      if RTEMP.1 == 1 then
            R20 = 100
      else
            R20 = 0
      endif
      RTEMP.1 = TEST (R2, R3)
      if RTEMP.1 == 1 then
            R21 = 200
      else
            R21 = 0
      endif
      exit
      sub BIT(TEST)(REG1, REG2)
            REG1 = REG1 / 2
            REG2 = REG2 / 4
            if REG1 > REG2 then
                  TEST = 1
            else
                  TEST = 0
            endif
      endsub
```

#### endscript

endscript

The following script o script is a combination of the previous two examples. This script uses a function having as input parameters a value (REG) and a bit (ENABLE), therefore declared by BIT(ENABLE); the function returns a bit (TEST), therefore declared by BIT(TEST) ( REG1, BIT(ENABLE) ).

```
script 3
      TRIGGER = 5
      V17 = TEST(R50, V1)
      V18 = TEST(R51, V2)
      V19 = TEST(R52, V3)
      V20 = TEST(R53, V4)
      exit
      sub BIT(TEST) ( REG, BIT(ENABLE) )
            if ENABLE == 1 then
                  REG = REG / 2
                  if REG > 100 then
                        TEST = 1
                  else
                        TEST = 0
                  endif
            else
                  TEST = 0
            endif
      endsub
```

## 3.2.10- WORD(x) and pointers

The word(x) function returns the number (address) of the Word containing the parameter x, where the parameter x is intended to be an input, an output, a virtual point, a register or a counter as in the following examples:

```
A1 = WORD(I18:2) // returns the number of the Word containing I18 channel 2
A2 = WORD(I18:2.1) // returns the number of the Word containing I18:2.1
A3 = WORD(O93) // returns the number of the Word containing O93 channel 1
A4 = WORD(V46) // returns the number of the Word containing V46
A5 = WORD(R37) // returns the number of the Word containing R37
A6 = WORD(C42) // returns the number of the Word containing C42
```

The following script shows how to use the **WORD (x)** function and the pointers. Suppose that the application requires a script that, every 2 seconds, counts how many registers, in the range R0 to R10, contain a value other tan zero; the results (the amount of register !=0) must be placed into register R15.

The function WORD(R0) returns the number of the Word where register R0 is located. The script defines a variable (in this example its name is ptr) that at the beginning is equal to the Word number of register R0. The notation [ptr] (inside square brackets) returns the content of the "pointed" register. In the following script, the R15 value will be increased by 1 every time the content of each register addressed in the loop is other than zero. At each iteration, the value of the pointer will be increased by 1 in order to point to the next Word and therefore to the next register. The notation ptr += 1 is equivalent to ptr = ptr + 1, as R15 = R15 + 1 can be written as R15 +=1.

When the pointer become greater than the address of R10, the loop will be interrupted and the script ends.

#### endscript

Another example: the day of the month is located in the Word 1924 (see RAM map); to copy this value (and therefore the containing of the Word 1924) to register R2, the following instruction can be written:

```
ptr = 1924
R2 = [ptr]
```

On the contrary, it is possible to copy the containing of R2 in the Word 1924 as follows:

Rel.: 1.2 October 2018

```
ptr = 1924
[ptr] = R2
```

The pointer are useful when the Word to be accessed to (both for reading and writing) cannot be identified in other ways (in other words when it cannot be identified by notations as Cx, Ry, etc.).

## 3.2.11- @RAM k and @WORD k

The functions @RAM k and @WORD k allow to access to pairs of RAM locations or single Words. The specified value (k) is the starting RAM address or the Word number and must be a constant value in the range 0 to 65535 in the first case and 0 to 32767 in the second one.

For instance, the day of the month is mapped in RAM memory at the address 0x0F08-0x0F09, corresponding to Word 1924; to copy this value (therefore the content of the Word 1924), for instance, into register R2, the following notations can be used: R2 = @RAM0x0F08 or R2 = @WORD1924.

On the other hand, the Word content can be also written: <code>@RAMOxOFO8 = R2</code> or <code>@WORD1924 = R2</code>
These functions are useful when the Word to be accessed to (both for reading and writing) cannot be identified in other ways (in other words when it cannot be identified by notations as Cx, Ry, etc.) and they are an option to the pointer method described before.

## 3.2.12 - SWAP(x)

The SWAP (x) function exchange the high byte with the low byte of the specified Word (x). The Word can be specified in one of the following ways:

- 1. directly by its symbolic name (e.g. R34, C48, Al24:3, etc.)
- 2. directly by @WORD or @RAM
- 3. by pointer

```
Examples of the first way:

R0 = SWAP(I18:2)

R1 = SWAP(R1)

Examples of the second way:

R66 = SWAP(@WORD1924)

Examples of the third way:

ptr = 1924

R45 = SWAP([ptr])
```

# 3.2.13- RANDOM(0)

The RANDOM (0) function returns a random number. The number is generated according to a particular algorithm (Lehmer Random Number Generator) which returns a pseudo random value uniformly distributed. The parameter passed to the RANDOM function must be always zero.

The following script call the RANDOM(0) function every 60 seconds and the returned random value will be copied to R0.

```
script 1
     trigger = 60
     R0 = RANDOM(0)
Endscript
```

## 3.2.14-BMASK(x)

The **BMASK**( $\mathbf{x}$ ) function returns a 16-bit number having, in its binary format, only one bit set to 1 at the position of ( $\mathbf{x}$ -1)%16. This notation means ( $\mathbf{x}$ -1) module 16 and it is equivalent to the remainder of the division of ( $\mathbf{x}$ -1) by 16. The **BMASK**( $\mathbf{x}$ ) function is therefore a mask which can be useful for bit operations.

The script in the following example calls 4 times a subroutine which must set or reset a virtual point if the value of a register is respectively greater or less than a constant value; since both the virtual point and the register and the constant value change at each call, then these parameters have to be passed to the subroutine. **Since the virtual point has to be written**, then this parameter should be passed as reference, but this is not allowed because it is a bit (see paragraph SUBROUTINEs and FUNCTIONS).

This is a typical case requiring the BMASK(x) function. Therefore the calling passes to the subroutine the address of the Word containing the virtual point (WORD (Vn)) and the mask allowing to identify, in the Word, the position of the bit related to that virtual point (BMASK(n)).

To set the virtual point, the subroutine executes the OR between the Word containing the point and the mask (which, as said, contains only one bit set to 1 at the position of the bit related to the desired point).

To reset the virtual point, the subroutine executes the AND between the Word containing the point and the complement of the mask (which therefore will contain only one 0 at the position of the bit related to the desired point).

The **BMASK** (x) function can be applied to any other bit parameter; the following example is very similar to the previous one, but on the contrary the subroutine switch ON and OFF real outputs instead of virtual points.

```
script 1
      trigger = 1
      call TEST(R0, 50, WORD(01.5), BMASK(5))
      call TEST(\mathbb{R}^1, 100, WORD(\mathbb{O}^{1.6}), BMASK(6))
      call TEST (\mathbb{R}^2, 150, WORD (\mathbb{O}^{1.7}), BMASK (7))
      call TEST(R3, 200, WORD(O1.8), BMASK(8))
      exit
      sub TEST(REGIN, KAPPA, [WOUT], MSK)
             if REGIN > KAPPA then
                    WOUT = WOUT | MSK
                                               // output ON
             else
                    WOUT = WOUT & !MSK
                                               // output OFF
             endif
      endsub
```

Rel.: 1.2 October 2018

endscript

endscript

#### 4- PROGRAM WRITING

The program writing is the first step of the MCP 4 controller. The equations, SCRIPTs, and all concerning the operating program, must be written according to the related syntax as described in the previous paragraphs.

To write a program for MCP 4, the software package **MCP IDE** (Integrated Design Environment) has to be used; this package is provided free of charge by **DUEMMEGI** together to MCP 4 module. This program must be installed on a Personal Computer with the following minimum characteristics:

- operative system WINDOWS® XP, 7 or 8
- processor with 1000MHz clock minimum
- 512M RAM memory
- HD with 50MB free space
- Video with graphic resolution 1024x768 pixel minimum
- mouse

MCP IDE, in addition to the program writing support, allows all operation related to the setting up an to the maintenance. For more details on the using of this program, refer to the related documentation.

Essentially, MCP IDE software tool includes:

- > a te4 editor to write the program, the SCRIPT, the configuration, MACRO, etc.
- a compiler to allow the translation of an ASCII file, containing the operating information, in a binary file adequate to be transferred in the non volatile memory (FLASH type) of MCP 4 module
- an section to transfer the program from the PC to MCP 4 (or vice-versa)
- MCP VISIO, that is a graphical utility to display the status of the plant (input and output modules, counters, virtual points, registers, etc.)
- > a simulator to verify the written program, or a part of it, before to transfer it into MCP 4 memory

The file containing the program is in ASCII format and must have the **.EQU** (or **.EXT**) extension; for instance:

#### filename.EQU

where *filename* is the name of the program file and may be any name allowed by the WINDOWS® syntax. The **.EQU** extension is mandatory because the following steps of MCP 4 programming (compiling and transferring) require that the source file have that extension.

MCP 4 controller programming takes place in a 3 sequential steps, through the MCP IDE support:

- building (or editing) of the filename.EQU file, containing the operating program in readable format (ASCII)
- compiling of *filename*.EQU, that is the conversion of the ASCII file in the related *filename*.BIN written in a format ready to be transferred into MCP 4 memory
- uploading of *filename*.BIN into MCP 4 memory

If some syntax errors are detected during the step 2, these ones will be reported by the compiler, together to some information about the error type and the line number where the error occurs.

# 4.1- Rule for program writing

The program must be written according to the syntax described in its relevant paragraph (logic, counter, timer, etc. ...). To write and compile a program, it is not necessary to connect MCP 4 controller to PC.

Rel.: 1.2 October 2018

**DUEMMEGI** s.r.l. - Via Longhena, 4 – 20139 MILANO Tel. 02/57300377 - Fax 02/55213686 – www.duemmegi.it

The following rules have to be observed:

- Spaces and TAB characters have no significance. They will be ignored by the compiler but the use of some space characters between the terms of an equation or other are strongly recommended for a best readability of the program
- An equation (but not a line in a SCRIPT) can be broken on several lines using the symbol \ (backslash) at the line end to specify that the equation will continue on the next line
- The equation finishes at the end of the line (if the \ symbol is not specified)
- The // symbol (two slashes) declares that the following words, until the line end, are comments, and so they will be ignored by the compiler. The comments are very useful for best readability and documentation of the program file. The use of the comment is strongly recommended to describe each equation in the program
- Both upper case and lower case characters can be used during the equation writing

Instead of the input and output symbols (Ij.k, Ox.y, Vn, Aj), it is possible to employ some variable names defined by the programmer through the define directive as here below described:

The previous equation is fully equivalent to:

```
01.1 = I1.1
```

but it can be easily interpreted. The variable names defined through the **define** directive cannot contain spacing characters. In addition, the compiler will ignore upper or lower case.

The following example shows a possible and simple program using the define:

```
// Definitions ///////
define
              StairLight
                              01.1
                              I1.1
define
              Floor1Button
define
                              I1.2
              Floor2Button
define
              Floor3Button
                              I1.3
// Define a virtual point as OR of each button (parallel connection)
V1 = Floor1Button | Floor2Button | Floor3Button
// Light Output
StairLight = TIMER (V1, 0, 450)
```

In the above example there are 3 buttons, one per each floor of a building; the pressing of a button switches on the stair light. This light will remain on during 45 seconds after the button release, then it will be automatically switched off thanks to the TIMER function. The same program may be written without using the definition of variable names as follows:

```
// Command by the buttons
V1 = I1.1 | I1.2 | I1.3

// Light output
O1.1 = TIMER (V1, 0, 450)
```

Note that using the **define** directive, the program has a best and mnemonic readability. About the using of the **define** directive in the SCRIPT, refer to the related chapter.

## 4.2- Compiling the program

The compiling is the second step of MCP 4 programming process. The file containing the program (.EQU extension) must be compiled through the proper menu item of MCP IDE utility.

The compiler processes the written equations, checks the syntax and the congruence, warns the errors if any and links the data in a binary file which name is the same as the .EQU file but with .BIN extension. The binary file is not in a printable format but it is adequate to be transferred in the MCP 4 memory.

To write and compile a program, it is not necessary to connect MCP 4 controller to PC.

If during the compiling process one or more errors occur, they will be displayed on the screen of the PC in a proper window and the program continues to check all other equations.

The compiler may also reports some WARNINGs: this means that no errors have been detected but there are some points to be verified before to upload the program to MCP 4 memory.

## 4.3- Uploading the program to MCP 4 memory

Last step of MCP 4 programming process is the **uploading to its flash MEMORY of the binary file** containing the system configuration and the program code. This is the third and last step after having written and copiled the program.

The uploading is made by the proper menu item of MCP IDE utility trough the RS232 port of PC connected to the MCP 4 serial port. The program can be however transferred also through the RS485 port or through the LAN network (using, for instance, the WEBS module in bridge mode).

The uploading of the program requires that MCP 4 controller be supplied and connected to PC, normally by means of the proper cable provided with MCP 4.

A new program transferred to MCP 4 is stored in a different memory location and therefore, during the download, the program previously loaded continues to operate without interruption; only when downloading of the new program is completed, and if everything goes well, the automatic switch from the old program to the new one will be performed.

**DUEMMEGI** s.r.l. - Via Longhena, 4 – 20139 MILANO Tel. 02/57300377 - Fax 02/55213686 – www.duemmegi.it

## 5- SETTING UP

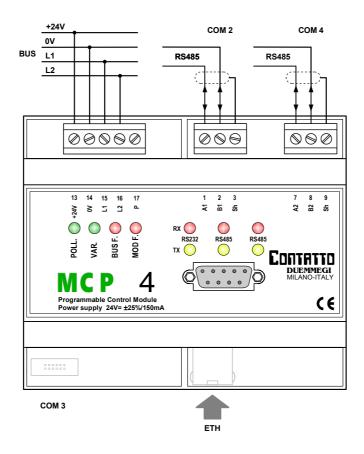

## 5.1- Connections

**MCP 4** module is available in DIN modular housing (6 modules size) and it provides a 5 poles removable terminal block for the connection to the bus.

MCP 4 features a serial RS232 port (COM1), two RS485 ports (COM2 and COM4), a dedicated port for special modules (COM3) and an Ethernet port (optional).

Following figures show the proper connections to be made and the description of the terminals; note that terminal 17 must be left unconnected.

#### Connections of MCP module

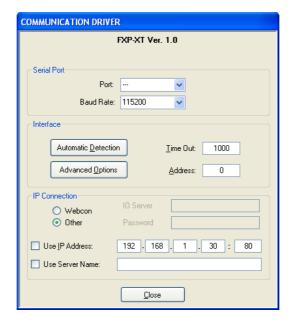

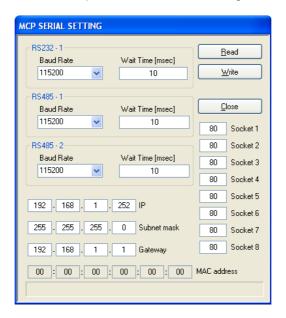

#### 5.2- Baud Rate selection

MCP 4 Baud Rate factory settings is fixed to 115200 Baud both for RS232 and the two RS485 ports; if for any reasons this speed has to be changed, use the software tool MCP IDE . Connect MCP 4 to the PC, supply it, and launch MCP IDE. Select from the menu "Communication", "Enable". The following window will appear:

Select the port (e.g. COM1) or press the button Automatic Detection to execute the automatic search of MCP 4 on the serial ports. Press then Advanced Options button; the following window will appear:

Press Read to read the current MCP 4 setting for the Baud Rate on RS 232 and RS485 ports. The other three parameters (Wait Time) are the delay time before the answer of MCP 4 to a Host request; these wait times are suggested to be not changed, if not really needed.

Choose the wanted Baud Rate for each port and then press the Write button to transfer the new setting to MCP 4. Finally, press the Close button; take in account that, when changing the Baud Rate of the port to which the PC is currently connected to, a new communication enable procedure at the new Baud Rate is needed. The allowed Baud Rates are: 2400, 4800, 9600, 19200, 38400, 57600, 115200.

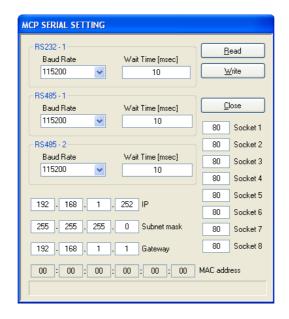

## 5.3- TCP/IP parameters settings (Ethernet)

For configuring TCP/IP parameters it is possible to proceed in several ways, two of which are here below described.

#### 1- Through RS232 serial connection between the PC and MCP4/ETH

This is the preferred method because it does not depend on the configuration of the network where MCP4/ETH has to be installed.

Connect the PC to the RS232 port of MCP4/ETH (if required via a USB-RS232 converter). Open the configuration panel by selecting, from MCP Ide menu, *Communication*, *Enable Communication* and open the communication with MCP4/ETH; then select *Advanced Options*: the following window will be shown:

The shown values are the default ones. Enter the desired parameters (IP address, Subnet mask, Gateway and ports for the different sockets), then push the Write button. At this point MCP4/ETH will be visible on the network with the set parameters, provided that they are compatible with the network configuration. The Read button allows to report the MCP4/ETH current configuration and its MAC address.

## 2- Via LAN network and browser

MCP4/ETH has the factory settings as shown in the figure above, particularly IP address 192.168.1.252, ports number 80 for all sockets, Subnet mask 255.255.255.0 and Gateway 192.168.1.1.

If the network is already compatible with this set of parameters, it is possible to connect MCP4/ETH directly to the local network (making sure that the default IP address is not already used by another device on the network) and change these settings as desired using the "Contatto Web Server" integrated in MCP4/ETH. The "Contatto Web Server" of MCP4/ETH can be accessed by using any browser (Firefox, Internet Explorer, Google Chrome, etc.). Enter into the current IP address of MCP4/ETH in the bar address of the browser (the default is 192.168.1.252) followed by /webmenu.htm, for example:

192.168.1.252/webmenu.htm

The main page of "Contatto Web Server" will be shown. Select <u>LAN Configuration</u> to access the sub-page of TCP/IP parameters setting.

## 5.4- RS232 and RS485 serial ports of MCP 4

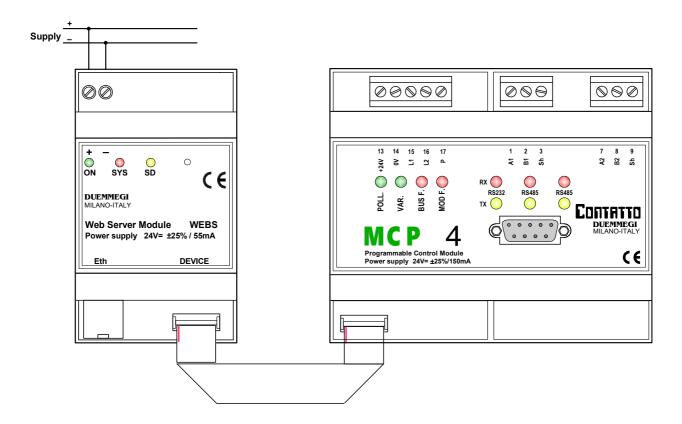

MCP 4 provides both RS232 (COM1, on the front panel) and RS485 serial ports (COM2 and COM4, terminals 1-2-3 and 7-8-9). These ports are **electrically insulated from the bus** by means of some internal opto-couplers and a dc/dc converter (no additional external power supply is required).

However, RS232 and RS485 ports are not insulated each one to the other.

**WARNING:** as for all RS485 networks, *radial connections must be avoided*; in addition, RS485 line *must be loaded, both at the beginning and at the end, by a 120 Ohm 1/2W resistor* between terminals A and B. The maximum number of device that can be connected on RS485 line must be limited to 32.

## 5.5- WEBS communication port

MCP 4 features a special communication port (COM3, under the terminal cover on the bottom left side, see following figure) for the connection to WEBS module, providing both Web Server functions and bridge function to interface MCP 4 to a LAN network (Ethernet). For more details refer to the technical sheet of WEBS module.

#### 6- DIAGNOSTICS

## 6.1- Diagnostics of CONTRITO system through MCP 4

MCP 4 module provides the failure warning through two red LEDs on the front panel.

**The red LEDs** report the alarms related to module failure (**MOD.F**) and bus failure (**BUS.F**). The MOD.F signaling occurs after 5 seconds delay time in respect to the moment of the failure of a module. The search of fault modules may be done using the MCP IDE software package, primarily displaying the map of the plant on MCP VISIO.

If both MOD.F and BUS.F LEDs lights in continuous mode, this means that MCP 4 memory is not correctly programmed.

If a BUS FAILURE occurs, the bus connections have to be checked. This failure appears when MCP 4 is not able to transmit on the bus (L1 and L2).

**Two green LEDs** on MCP 4 panel report the bus activity: the **POLL** led shows the start of the polling cycle and it blinks at a frequency inversely proportional to the number of configured modules (with few connected modules this LED may seem to be fixed ON).

The VAR led shows, through a flsh, the occurrence of a status change on one or more input modules.

If the VAR LED remains ON for a long time (greater then 2 seconds), then two or more modules of the same type (IN or OUT) have the same address; in this case use MCP VISIO utility to find the doubled addresses (the doubled modules are displayed on the screen in yellow color). The doubled addresses signaling, however, cannot be assured, because if the answer of the two modules is exactly superimposed each one to the other, then MCP 4 cannot detect the anomaly.

During the firmware update of the main microcontroller inside MCP 4 the two red LEDs flash alternately, while during the firmware update of the secondary microcontroller the two green LEDs flash alternately.

Three pairs of LEDs (red and yellow) on the front panel of MCP 4 allow to monitor the activity, if any, on the related serial ports RS232 and RS485.

The following table resumes the signaling in the various operating status:

| Operating status                            | POLL                           | VAR  | BUS.F     | MOD.F      |
|---|--------------------------------|--|-----------|------------|
| Normal                                      | Periodic blinking              | Flash at the occurrence of a change on an input module | Fixed OFF | Fixed OFF  |
| Module failure                              | Periodic blinking              | Flash at the occurrence of a change on an input module | Fixed OFF | Fixed ON   |
| Double address                              | Periodic blinking              | ON for long time                                       | Fixed OFF | Х          |
| Bus failure                                 | Fixed OFF                      | Fixed OFF  | Fixed ON  | Fixed OFF  |
| FLASH not programmed                        | Simultaneous p                 | eriodic blinking                                       | Fixed ON  | Fixed ON   |
| Update of main microc. or FW not valid      | Simultaneous periodic blinking |  | Alternate | e blinking |
| Update of secondary microc. or FW not valid | Alternate                      | e blinking   | Х         | Х          |

**Note:** The frequency of periodic blinking of POLL may be so high that LED seems to be fixed ON. X = don't care.

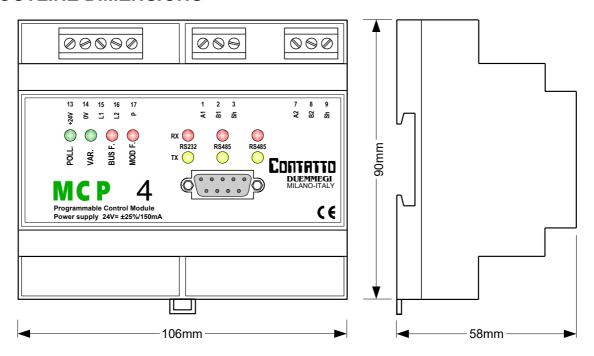

## 7- TECHNICAL CHARACTERISTICS

| Power supply voltage                           | 24V <del></del> ± 25%                                    |
|--|--|
| Max current consumption                        | 150mA  |
| Number of internal processors                  | 2  |
| Automatic switch standard/daylight saving time | Yes  |
| Typical input to output reaction time          | 25msec   |
| User program memory size                       | FLASH type 16 MBytes                                     |
| RAM Memory size                                | 256 KWords   |
| Allowable virtual points                       | 2032   |
| Allowable registers                            | 1024, 16-bit each one                                    |
| Allowable timers                               | 512 with times 0 to 6553 seconds, resolution 0.1 sec.    |
| Allowable counters                             | 1024, 16-bit each one                                    |
| Programming clock                              | Daily, Weekly, Yearly                                    |
| Integrated advanced scheduler                  | Weekly   |
| Integrated WEB Server                          | Yes (if Ethernet port installed)                         |
| Allowable input addresses                      | 127 addresses, 4 channel for address, 16-bit for channel |
| Allowable output addresses                     | 127 addresses, 4 channel for address, 16-bit for channel |
| Available communication ports                  | 1 x RS232 opto-coupled                                   |
|  | 2 x RS485 opto-coupled                                   |
|  | 1 x dedicated port                                       |
|  | 1 x Ethernet port (optional)                             |
| Peripheral devices handling                    | - Touch screen video terminals                           |
|  | - Bus display with alarm handling                        |
|  | - SCADA Supervision systems on PC                        |
| Interfacing to other systems                   | Through MODBUS RTU and MODBUS TCP/IP protocols           |
| Housing  | Modular box 6M for DIN rail mounting                     |
| Operating temperature                          | -5 ÷ 50 °C   |
| Storage temperature                            | -20 ÷ 70 °C  |
| Protection degree                              | IP20   |

Warning: MCP 4 module contains a rechargeable battery: remove this battery if throwing out the device. The battery must be eliminated in a safe way according to current laws.

## 8- OUTLINE DIMENSIONS

## 9- FXP-XT COMMUNICATION PROTOCOL

## 9.1- Messages format ad meaning

The proprietary protocol implemented into MCP 4 is named **FXP-XT** protocol; this protocol, has been specifically developed to interface MCP 4 to external world (PC, PLC, etc.) and it is **NRZ with 1 start bit, 8 data bit, no parity, 1 stop bit**. The baud rate can be selected as follows: 2400, 4800, 9600, 19200, 38400, 57600, 115200 baud. **MCP acts as a slave unit**, then it only answers to the requests of a HOST device. In the following, the numerical data represented with the **0x** notation are intended to be in the hexadecimal format.

The messages between MCP 4 and HOST have the following format:

| Address C | Code #Byte | Data 1 |  | Data N | ChkSum H | ChkSum L | 1 |
|-----------|------------|--------|--|--------|----------|----------|---|
|-----------|------------|--------|--|--------|----------|----------|---|

#### Where:

• Address: 1 byte, node address of MCP 4; the address 0x00 is valid for any node address

Code: 1 byte, it specifies the function of the message
# Byte: 1 byte, number of bytes in the following data field

• Data 1 ÷ N N data bytes

• ChkSum: 2 bytes (high, low) of checksum, equal to the complemented sum of the message

bytes, including the address, the code and the number of bytes.

The available messages are:

#### **HOST to MCP requests**

| Code | # Byte  | Data Bytes  | Description  |
|------|---------|---|--|
| 0x7F | 4       | Add_U, Add_H, Add_L, N                              | Reading from RAM memory of N bytes (1÷255), starting from address specified by the first 3 data bytes. N=0 means reading of 256 bytes.                     |
| 0x7E | 5 ÷ 256 | Add_U, Add_H, Add_L, N, Data1<br>DataN              | Writing to RAM memory of N bytes (1÷252) starting from address specified by the first 3 data bytes. (Note 1)   |
| 0x7D | 4       | Add_U, Add_H, Add_L, N                              | Reading from microcontroller memory of N bytes (1÷255) starting from address specified by the first 3 data bytes. N=0 means reading of 256 bytes. (Note 2) |
| 0x7C | 5 ÷ 256 | Add_U, Add_H, Add_L, N, Data1<br>DataN              | Writing to microcontroller memory of N bytes (1÷252) starting from address specified by the first 3 data bytes. (Note 2)                                   |
| 0x7B | 2       | Mod_Add, N  | Reading of N (1÷32) output modules starting from module address Mod_Addr.  |
| 0x7A | 2       | Mod_Add, N  | Reading of N (1÷32) input modules starting from module address Mod_Addr.   |
| 0x79 | 6       | Mod_Addr, Ch, Status_H, Status_L,<br>Mask_H, Mask_L | Writing of a channel (Ch = 1÷4) of an output module (Mod_Addr=1÷127). The mask (bit set to 1) identifies which output points have to be modified.          |
| 0x78 | 3       | V_H, V_L, Status                                    | Virtual point writing. V_H-V_L is the point number (1÷2032), Status can be 0x00 (for Vx=0) or 0x01 (for Vx=1).   |
| 0x70 | 2       | 'ID'  | ID request. The data field contains the ASCII code of the two characters 'I' and 'D' (therefore 0x49 and 0x44).  |

**Note 1:** If a writing operation modifies an output, a virtual point, a register, a counter, etc., then the command will be executed when the less significant byte of the Word is written, while no command is executed when writing the most significant byte of the Word. **Note 2:** To read/write the EEPROM memory of MCP4, the messages 0x7D/0x7C with address starting from 0x7FF000 have to be used.

## MCP to HOST answers

| Code | # Byte  | Data Bytes  | Description  |
|------|---------|---|--|
| 0x7F | 1 ÷ 256 | Data1DataN  | Answer to reading message of N bytes from RAM memory.  |
| 0x7E | 1       | 0xFF if writing OK 0x00 se writing KO  Answer to writing message of N bytes memory. |  |
| 0x7D | 1 ÷ 256 | Data1DataN  | Answer to reading message of N bytes from microcontroller memory.  |
| 0x7C | 1       | 0xFF if writing OK<br>0x00 if writing KO  | Answer to writing message of N bytes to microcontroller memory.  |
| 0x7B | 8 ÷ 256 | Data1Data(Nx8)  | Answer to reading message of N (1÷32) output modules starting from address module Mod_Addr. The answer contains Nx8 bytes in the data field. The meaning of each block of 8 bytes is the following:  Data1-Data2: CH1 of module Mod_Addr Data3-Data4: CH2 of module Mod_Addr Data5-Data6: CH3 of module Mod_Addr Data7-Data8: CH4 of module Mod_Addr |
| 0x7A | 8 ÷ 256 | Data1Data(Nx8)  | Answer to reading message of N (1÷32) input modules starting from address module Mod_Addr. The answer contains Nx8 bytes in the data field. The meaning of each block of 8 bytes is the following:  Data1-Data2: CH1 of module Mod_Addr Data3-Data4: CH2 of module Mod_Addr Data5-Data6: CH3 of module Mod_Addr Data7-Data8: CH4 of module Mod_Addr  |
| 0x79 | 1       | 0xFF if writing OK<br>0x00 if writing KO  | Answer to channel writing (Ch = 1÷4) of an output module (Mod_Addr=1÷127).   |
| 0x78 | 1       | 0xFF if writing OK<br>0x00 if writing KO  | Answer to writing message of a virtual point.  |
| 0x70 | 68      | FV1_H, FV1_L, FV2_H, FV2_L, ID1ID64   | Answer to the identification code request. Bytes FV1_H ÷FV2_L return the version number of the firmware loaded into MCP 4.  ID1÷ID64 are the ASCII codes of the 64 characters of the identification string.  |

# 9.2- RAM memory mapping

The following table describes the RAM mapping of MCP 4 for the commonly used parameters.

**Notes:** Unspecified RAM locations in the following table are intended to be reserved or not used. When using **MODBUS RTU** protocol, the number of each Word in the table of next paragraph must be increased by 1 IF AND ONLY IF the **MODBUS-** option was used (see 2.1.4).

## 9.2.1- Main RAM memory mapping

| Byte<br>(HEX) | Word<br>(DEC) | Description                                     | Comments   |
|---------------|---------------|---|--|
| 0002÷00FF     | 1÷127         | Status or value of CH1 of input modules         | Each status or value takes 1 Word. The input modules are 127. (Note 1)   |
| 0102÷01FF     | 129÷255       | Status or value of CH2 of input modules         | Each status or value takes 1 Word. The input modules are 127. (Note 1)   |
| 0202÷02FF     | 257÷383       | Status or value of CH3 of input modules         | Each status or value takes 1 Word. The input modules are 127. (Note 1)   |
| 0302÷03FF     | 385÷511       | Status or value of CH4 of input modules         | Each status or value takes 1 Word. The input modules are 127. (Note 1)   |
| 0402÷04FF     | 513÷639       | Status or value of CH1 of output modules        | 127. (Note 1)  |
| 0502÷05FF     | 641÷767       | Status or value of CH2 of output modules        | 127. (Note 1)  |
| 0602÷06FF     | 769÷895       | Status or value of CH3 of output modules        | 127. (Note 1)  |
| 0702÷07FF     | 897÷1023      | Status or value of CH4 of output modules        | 127. (Note 1)  |
| 0902÷09FF     | 1153÷1279     | Map of the virtual points                       | 2032 virtual points (digital only) organized as block of 16 points for each Word (8 points for per byte). (Note 2) |
| 0A00÷0A27     | 1280÷1299     | Scheduler management                            | See paragraph 9.2.2 for details  |
| 0F00÷0F01     | 1920          | Hours in BCD format                             | Read from the MCP 4 timekeeper chip. (Note 3)  |
| 0F02÷0F03     | 1921          | Minutes in BCD format                           | Read from the MCP 4 timekeeper chip. (Note 3)  |
| 0F04÷0F05     | 1922          | Seconds in BCD format                           | Read from the MCP 4 timekeeper chip. (Note 3)  |
| 0F06÷0F07     | 1923          | Day of the week in BCD format                   | Read from the MCP 4 timekeeper chip.<br>1=Monday, 2=Tuesday,7 (or 0)=Sunday. (Note 3)                              |
| 0F08÷0F09     | 1924          | Day of the month in BCD format                  | Read from the MCP 4 timekeeper chip. (Note 3)  |
| 0F0A÷0F0B     | 1925          | Month in BCD format                             | Read from the MCP 4 timekeeper chip. (Note 3)  |
| 0F0C÷0F0D     | 1926          | Year in BCD format                              | Read from the MCP 4 timekeeper chip. (Note 3)  |
| 0F10÷0F11     | 1928          | Amount of binary events in the queue            | Read only.   |
| 0F12÷0F13     | 1929          | Amount of binary events to be deleted           | How many consecutive events must be deleted in the queue.  |
| 0F14÷0F15     | 1930          | Pointer to the first binary event               | It is the address of the first event after last deleting.  |
| 0F16÷OF17     | 1931          | Amount of analog event in the queue             | Read only.   |
| 0F18÷0F19     | 1932          | Amount of analog events to be deleted           | How many consecutive events must be deleted in the queue.  |
| 0F1A÷0F1B     | 1933          | Pointer to the first analog event               | It is the address of the first event after last deleting.  |
| 1000÷17FF     | 2048÷3071     | Map of the general purpose registers            | R0÷R1023. 1 Word for each register.  |
| 1800÷1FFF     | 3072÷4095     | Map of the counters                             | C0÷C1023. 1 Word for each counter.   |
| 2000÷2FFF     | 4096÷6143     | Map of the timer                                | TIMER0÷TIMER511. 4 Words for each timer, the first containing the current time and the other three reserved.       |
| 3000÷3FFF     | 6144÷8191     | Scheduler data                                  | See paragraph 9.2.2 for details  |
| 4000÷7FFF     | 8192÷16383    | List of binary events                           | 2048 events, 8 bytes for each event, total 16384 bytes.<br>(Note 4)  |
| A000÷BFFF     | 20480÷24575   | List of analog events                           | 1024 events, 8 bytes for each event, total 8192 byte.<br>(Note 5)  |
| E800÷E9FF     | 29696÷29951   | Information about configured modules            | 2 bytes for each modules, offset = 2 x (Module_ Address). (Note 6)   |
| EA00÷EAFF     | 29952÷30079   | Diagnostic information                          | 1 byte for each modules, offset = (Module_ Address). (Note 7)  |
| EB00÷EB7F     | 30080÷30143   | Reset of 16-bit external counter modules MODCNT | 1 byte for each modules, offset = (Module_ Address). (Note 8)  |

**Note 1:** Generally, for digital inputs and outputs, bit=1 means active status and bit=0 means non-active status. For analog modules, the Word contains the value referred to that channel. The less significant bit of a Word refers to point 1, the most significant bit refers to point 16.

**Note 2:** The less significant bit of the first Word in the map of virtual points (Word 1153) is the status of virtual point V1, the most significant bit of the same Word is the status of the virtual point V16, and so on for the next Words. Bit=1 means active status and bit=0 means non-active status. The virtual point n is the bit (n-1)%16 (n-1 module 16) of the Word 1153 + INT[(n-1)/16].

**Note 3:** These Words contain the current status of MCP 4 internal timekeeper chip; in addition to reading, these cells may be written and in this case the timekeeper chip will be updated with new passed parameters (also in MODBUS protocol). All Words related to the timekeeper information have the MSByte always set to zero, while the LSByte contains the related information (hh, mm, ss, day of the week, day, month, year) in BCD format.

**Note 4:** The binary event list can store up to 2048 events, and it is organized in blocks of 8 bytes for each event. Each 8-byte block (related to an event) is coded as follows:

| Bit 7  | Bit 6  | Bit 5                  | Bit 4 | Bit 3 | Bit 2         | Bit 1  | Bit 0 |
|--------|--------|------------------------|-------|-------|---------------|--------|-------|
|        |        |                        |       |       |               |        |       |
| VIRT   |        | Module Address (1÷127) |       |       |               |        |       |
| STATUS | SYS. F | Channel                | (0-3) |       | Point         | (0÷15) |       |
|        |        |                        |       | -     |               |        |       |
| -      | -      | - Hours                |       |       |               |        |       |
| -      | -      | Minutes                |       |       |               |        |       |
| -      | -      | Seconds                |       |       |               |        |       |
| -      | -      | -                      |       | D     | ay of the mon | th     |       |
| -      | -      | -                      | -     |       | Мо            | nth    | ·     |

- 1. If the bit VIRT is =1, then the specified address is referred to a virtual point
- 2. For virtual point Vn, n = ((Module Address) 1) x 16) + Point + 1
- 3. (SYS.F = 1) & (Module Address = 0) & (STATUS=1) means BUS.F
- 4. (SYS.F = 1) & (Module\_Address = 0) & (STATUS=0) means BUS. OK
- 5. (SYS.F = 1) & (Module\_Address <> 0) & (STATUS=1) means MOD.F
- 6. (SYS.F = 1) & (Module Address <> 0) & (STATO=0) means MOD.OK
- 7. The symbol means "not used"

**Note 5:** The list of analog events (values or codes) can store up to 1024 events, and it is organized in blocks of 8 bytes for each event. Each 8-byte block (related to an event) is coded as follows:

| Bit 7  | Bit 6                  | Bit 5   | Bit 4            | Bit 3        | Bit 2  | Bit 1 | Bit 0 |
|--------|------------------------|---------|------------------|--------------|--------|-------|-------|
|        |                        |         |                  |              |        |       |       |
| -      |                        |         |                  | e_Address (* | I÷127) |       |       |
|        | Value or Code (Byte H) |         |                  |              |        |       |       |
|        | Value or Code (Byte L) |         |                  |              |        |       |       |
| -      | -                      | -       |                  |              | Hours  |       |       |
| -      | -                      |         | Minutes          |              |        |       |       |
| Channe | 1(0-3)                 | Seconds |                  |              |        |       |       |
| -      | -                      | -       | Day of the month |              |        |       |       |
| -      | -                      | -       | - Month          |              |        |       |       |

The symbol – means "not used".

**Note 6:** The configuration map (bytes 0xE800÷0xE9FF) contains the information related to the bus modules included in the polling cycle of MCP 4. The information is organized in two bytes for each module with offset = 2x(Module Address) as follows:

```
offset 0 (Bytes 0xE800÷0xE801): not used offset 2 (Bytes 0xE802÷0xE803): input module 1 offset 4 (Bytes 0xE804÷0xE805): input module 2 ....... offset 254 (Bytes 0xE8FE÷0xE8FF): input module 127 offset 256 (Bytes 0xE900÷0xE901): not used offset 258 (Bytes 0xE902÷0xE903): output module 1 ...... offset 510 (Bytes 0xE9FD÷0xE9FF): output module 127
```

                                                                                                      means
          bit 13÷11: Type of module:
                    0 = No module
                    1 = 8-bit module, 1st generation
                    2 = 16-bit module, 1st generation
                    3 = 1-channel 16-bit module, 2nd generation
                    4 = multiple channels 16-bit module, 2nd generation
(***)
          bit 10÷0: virtual point (if needed) for module failure information, in the format Point/Address. Bits 6÷0 show the address,
          bits 10÷7 shows the point. The virtual point will be Vn, where n = ((bit6÷bit0) - 1) x 16) + (bit10÷bit7) + 1
```

**Note 7:** The map of diagnostic (bytes 0xEA00÷0xEAFF) contains the information related to the fault modules or related to modules with doubled address. The information are organized in one byte for each module with offset = Module Address as follows:

```
offset 0 (Byte 0xEA00): not used
offset 1 (Byte 0xEA01): input module 1
offset 2 (Byte 0xEA02): input module 2
.......
offset 127 (Byte 0xEA7F): input module 127
offset 128 (Byte 0xEA80): not used
offset 129 (Byte 0xEA81): output module 1
......
offset 255 (Byte 0xEAFF): output module 127

The meaning of the bits is the following:
    bit 7: not used
    bit 6: not used
    bit 5: doubled address
    bit 4: module failure
    bit 0÷3: counter of the consecutive loss answers
```

Note 8: This map (bytes 0xEB00÷0xEB7F) can be used to reset the external counter modules MODCNT (if installed). The information are organized in one byte for each MODCNT module, with offset = Module Address as follows:

```
offset 0 (Byte 0xEB00): not used
offset 1 (Byte 0xEB01): input module MODCNT 1
offset 2 (Byte 0xEB02): input module MODCNT 2
......
offset 127 (Byte 0xEB7F): input module MODCNT 127

The meaning of the bits of each byte in this map is the following:
    bit 7÷4: not used
    bit 3: reset channel 4
    bit 2: reset channel 3
    bit 1: reset channel 2
    bit 0: reset channel 1
```

# 9.2.2- RAM mapping of the Scheduler

Rel.: 1.2 October 2018

The Scheduler uses two blocks of RAM memory inside MCP4: Words 1280÷1299 and Words 6144÷8191. The first block is used to make parametric (and therefore easier) the reading and writing of a given day Dy of a given scheduler Sx (Dy= 1 (MON) to 7 (SUN) and Sx= 1 to 16). The second block contains instead all 8 ON and OFF times of all 7 days all of all 16 schedulers.

For the management by a supervisor or a WEB SERVER, it is advisable to act only on the first RAM block, leaving out where they are actually mapped the information of each scheduler: this approach greatly simplifies the work and makes it parameterizable through the specification of two values: the number of the scheduler ( $Sx = 1 \div 16$ ) and the day of the week ( $Dy = 1 \div 7$ ). When writing one of these two values, MCP 4 will copy the data related to the day Dy of the scheduler Sx in the first RAM block. Conversely, writing a value (eg. a time) in a Word of the first RAM block, MCP 4 will copy the data related to the day Dy of the scheduler Sx from this block RAM to its actual position in the second RAM block.

| Byte<br>(HEX) | Word<br>(DEC) | Contenuto                                      | Commenti  |
|---------------|---------------|--|---|
| ` ,           | , ,           | BEGINNING OF BLOCK 1                           |   |
| 0A00÷0A01     | 1280          | 1st ON scheduling time                         | 1st Byte: hour (0÷24), 2° Byte: minutes (0÷59) if hour=24, the minutes must be = 0; also see (Note 1) and (Note 2). Writing a value in these Words, MCP will update the related scheduler data, pointed by Word 1297 (Scheduler nr. Sx) and 1298 (Day nr. Dy)   |
| 0A02÷0A03     | 1281          | 1st OFF scheduling time                        | Same as above   |
| 0A04÷0A05     | 1282          | 2nd ON scheduling time                         | Same as above   |
| 0A06÷0A07     | 1283          | 2nd OFF scheduling time                        | Same as above   |
|               |               |  |   |
| 0A1C÷0A1D     | 1294          | 8th ON scheduling time                         | Same as above   |
| 0A1E÷0A1F     | 1295          | 8th OFF scheduling time                        | Same as above   |
| 0A20÷0A21     | 1296          | Scheduling times enabling  Scheduler number Sx | The first 8 bits represent the enabling of the related scheduling time (Bit=0: sched. disabled, Bit=1: sched. enabled).  Bit0 = 1st scheduling time Bit1 = 2nd scheduling time Bit2 = 3rd scheduling time Bit3 = 4th scheduling time Bit4 = 5th scheduling time Bit5 = 6th scheduling time Bit6 = 7th scheduling time Bit7 = 8th scheduling time Writing a value 1 to 16 in this Word, MCP 4 will copy the data |
| 07.22 107.20  |               |  | of the day Dy of the schedule Sx in the Words 1280÷1296 (8 scheduling times ON-OFF + Enabling)  |
| 0A24÷0A25     | 1298          | Day number Dy                                  | Writing a value 1 (MON) to 7 (SUN) in this Word, MCP 4 will copy the data of the day Dy of the scheduler Sx in the Words 1280÷1296 (8 scheduling times ON-OFF + Enabling)   |
| 0A26÷0A27     | 1299          | Copy scheduler                                 | Writing any value in this Word, MCP 4 will copy the data of the current day to the next one (of the same scheduler Sx) and the day number Dy will be increased by 1 or, if it was 7, it will be set to 1  |
|               |               | END OF BLOCK 1                                 |   |
|               |               |  |   |
|               |               | BEGINNING OF BLOCK 2                           | <u> </u>  |
| 3000÷30FF     | 6144÷6271     | Data of scheduler 1                            | 128 Words   |
| 3100÷31FF     | 6272÷6399     | Data of scheduler 2                            | 128 Words   |
|               |               |  |   |
| 3F00÷3FFF     | 8064÷8191     | Data of scheduler 16                           | 128 Words   |
|               |               | END OF BLOCK 2                                 |   |

#### Note:

<sup>(1)</sup> It is possible to specify the time 24:00 if the controlled point must be ON across midnight, in order to avoid the switching OFF during a minute between 23:59 and 00:00.

<sup>(2)</sup> Hour values greater than 24 and/or minutes greater than 59 mean a not valid time.

# 10- MCP IDE: INTEGRATED DEVELOPMENT ENVIRONMENT FOR APPLICATIONS USING MCP 4

## 10.1- Description of the software package

MCP IDE (Rel 3.2.3 or higher) is an Integrated Development Environment to support the program development for Content MCP 4 controller. The MCP IDE package comes complete with an Editor, Compiler, Transfer utility, Simulator and Supervisor of the operation status of MCP 4 and of the plants. The package is made by several tool programs, as described here in the following.

- ➤ MCP IDE is the MCP 4 program editor, integrating the compiler, the configuration tools for special modules (e.g. ModTPD transponder reader module, ModHT room controller for hotel applications and so on) and the "write to / read from" MCP 4 utilities.
- ▶ MCP VISIO is a tool allowing the supervision of input and output modules and all other MCP 4 parameters (counters, registers, virtual points, etc.). This tool can work connected to MCP 4 through the serial port or it can simulate the program written by MCP IDE, in order to debug it before the writing into MCP 4 FLASH memory.
- > MCP MAP is an advanced tool allowing to access to the "heart" of MCP 4; the use of this tool is reserved to expert user only.
- > Controtto XT is an utility for the control of CONTRITO through the PC.

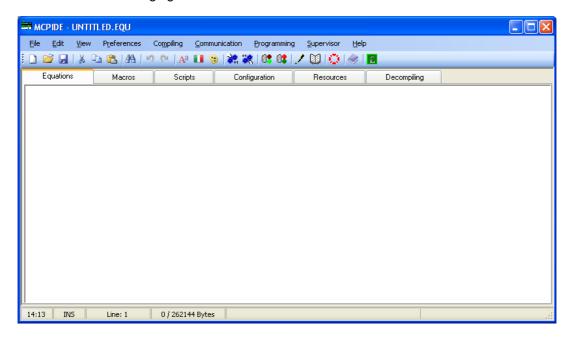

Rel.: 1.2 October 2018

To perform a firmware update of MCP 4 microcontrollers (other than all other **Duemmegi** devices), use the software package named **BootTools** which can be downloaded from **Duemmegi** site.

The ease of use of MCP IDE and its many features and utilities allow quick development and configuration of MCP 4 controller, according to the requirements of the plant where it will be installed. The intuitive operation and the clear menu items allow to start using MCP IDE immediately, allowing to save more time in developing applications and requiring less time reading user manuals.

## 10.2- MCP IDE

MCP IDE looks like the following figure:

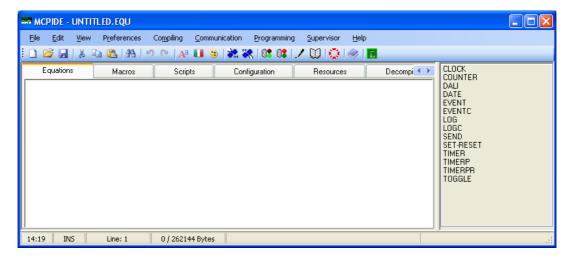

The main window of the program has 6 TABs (Workspaces): Equations, Macros, Scripts, Configuration, Resources and Decompiling. Each button on the button bar shows the description of its function simply placing the mouse cursor on the button itself.

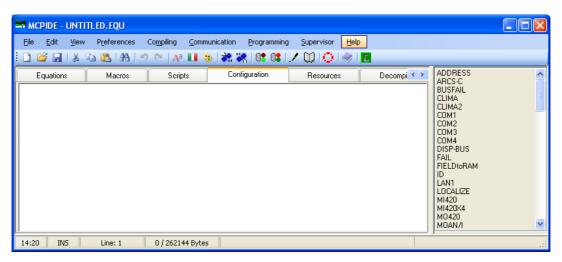

The majority of the buttons and menu items are so intuitive that no more explanations are needed.

The button (or the menu item View – Show Keywords List) is the "life belt" and it allows to switch ON or OFF the opening of a space, on the right side, containing all the keywords allowed in the related TAB:

When Configuration TAB is selected, then also a list of all available **CDITHTTO** modules will be shown:

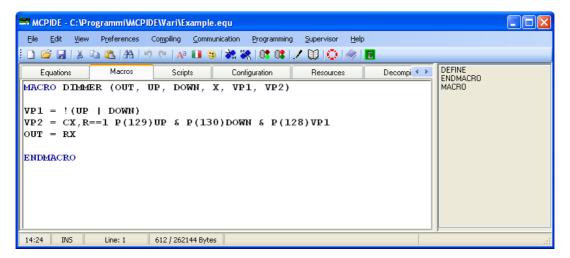

Double-clicking on one of the keywords in the life belt, the related example will be placed in the opened workspace; the inserted example must be completed as required.

The Equations workspace allows writing the standard equation of MCP 4:

```

Interface

FXP-XT Ver. 1.0

FW. 1.0: 1.0

Port: COM1

Baud Rate: 115200

Automatic  $\underline{D}$  etection

Advanced Options

Other

Use IP Address:

Use Server Name:

## 10.2.1- MCP IDE

The button open the serial communication with MCP 4, while the button closes it. The window appearing at the communication opening is that shown here. Once the communication has been enabled by the button Detect, an information similar to "FW - 1.0: 1.0" will be shown; the first number on the left side is the FW version of the main microcontroller of MCP 4 (1.0 in this example), while the number on the right side

is the FW version of the secondary microcontroller (1.0 in this example).

The label "FXP-XT Ver. 1.0" in the shown window is the version of the communication driver included in the MCP IDE package.

The "Time Out" is the maximum time that MCP IDE wait for an answer from MCP 4 and "Address" is the address assigned to the MCP 4 to be polled (take in account that specifying address zero the communication will take place regardless of the address assigned to MCP 4).

MCP IDE can also communicate with MCP 4 through the Ethernet network. In this case the communication can be enabled specifying "Other" and the IP address and the port of MCP4 (or another device interfacing MCP 4 to the netwotk) and then clicking in the "Use IP Address" check box. In this way MCP IDE will send the messages on the Ethernet port of the PC where it has been installed, instead to RS232 port. The answer of MCP 4, afterward, will follow the reverse way.

"Use Server Name" allows to specify an address provided by a DNS service (e.g. when accessing from WAN and MCP 4 is

installed in a LAN that communicates to the WAN through a dynamic IP).

Rel.: 1.2 October 2018

1000

Time Out:

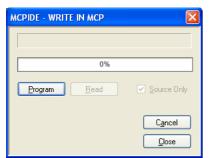

Address:

192 . 168 . 1 . 30 : 80

Another connection possibility is through Webcon: in this case, after having selected the related item, enter the IO Server name (generally Contatto) and the password, then enter the IP address and the port of Webcon and finally select "Use IP Address" (or enter the DNS service address and then select "Use Server Name"); for details, refer to Webcon user's manual.

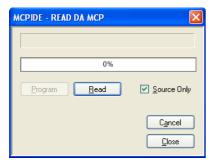

# 10.2.2- Program transferring

Close

Pushing the button or selecting the Write to MCP menu item, the window on this left side will be shown.

Push program to begin the transfer of current program to MCP 4.

Pushing the button or selecting Read from MCP, the reversed process will start; the window will on this left side appear.

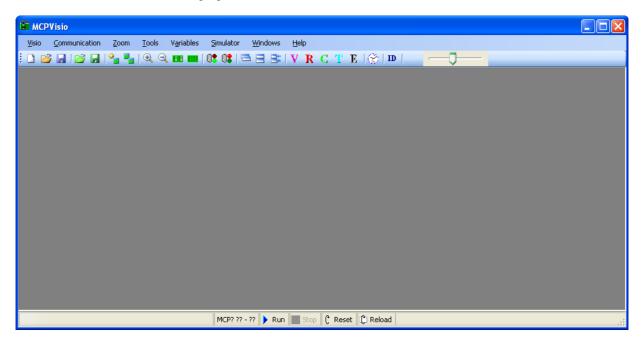

Enabling the "Source Only" option, the source program will be transferred as it has been created, including the comments; on the contrary, the whole FLASH contents will be downloaded to the PC. This last procedure requires many time and it is needed for specific reasons only (e.g. diagnostic).

#### 10.3- MCP VISIO

MCP VISIO looks like the following figure:

Each button on the button bar shows the description of its function simply placing the mouse cursor on the button itself.

The majority of the buttons and menu items are so intuitive that no more explanations are needed.

The button open the serial communication with MCP 4, while the button closes it.

**Note:** since the communication driver it the same for all the software package, if the serial communication has been opened from MCP IDE, then the communication results to be opened in MCP VISIO too and vice versa.

The buttons 

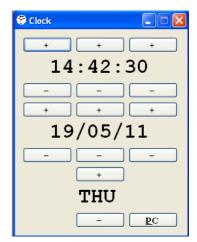

R C T E allow to display, respectively, the window of virtual points, registers, counters, timers and events (both digital and analog ones).

The reading/setting window (opened by the butto n) looks like in the figure on this right side. The clock panel shows Hours:Minutes:Seconds on the first line, Day/Month/Year on the second one and the Day of the Week on the third line.

If the serial communication with MCP 4 is opened, the related current time and date setting will be shown. If, on the contrary, the serial communication with MCP 4 is closed, then a sequence of dashes will be shown. The buttons + and - will increment and decrement the related item.

At every change in the setting using the buttons + and -, the setting of MCP 4 will be automatically updated.

The button PC transfers the date and time setting of the PC to MCP 4.

Visio Communication Zoom

New Group...
Open Group...

Save Group

New Project

Save Project

Exit

Open Project...

Save Project As..

Add Module To Group

Paste Module Into Group

Save Group As...

The button will show on the status bar, on the bottom side of MCP VISIO window, the firmware version of the connected MCP 4.

The Visio menu item allows the following operations:

New Group: open a new group (see in the following)

**Open Group**: load a saved group from file **Save Group**: save the current group to file

Save Group As: save the current group with different file name

New Project: open a new project (see in the following)

Open Project: load a saved project from file (see in the following)

Save Project: save the current project to file

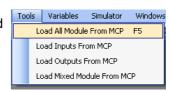

Save Project As: save the current project with different file name Add module To Group: add a module to the current group Paste Module Into Group: paste a module into the current group

Exit: quit the program

The Tools menu allows the following functions:

**Load All Modules From MCP**: create 3 groups (Inputs, Outputs and Mixed Modules)

Load Inputs From MCP: create a group for all configured Input Modules
Load Outputs From MCP: create a group for all configured Output Modules
Load Mixed Module from MCP: create a group for all configured Mixed Modules

Through these functions, the module configured in MCP 4 will be shown, provided that MCP 4 has been connected or the simulator has been activated (see in the following). As option, it is possible to create customized groups including input and output modules and virtual points; the procedure to create the groups will be now described.

The slider on the button bar allows to change the polling period from PC to MCP 4 (if connected). Moving the slider at left side, the period is lower (so the updating of the objects in the windows is fast). Moving it at right side the period increase (so the updating of the objects in the windows is slow).

# 10.3.1- The Groups of MCP VISIO

Select New Group from the Visio menu. A new window will be opened as in the following figure:

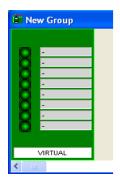

The input and output modules and the virtual points can be included in this window as desired. Press the button to add a module. The following window will appear:

Select one of the listed modules and specify the address in the related te4 box (for mixed and some special modules, both input and output address has to be specified).

To insert a virtual module (made by 8 points, assigned in any order) select VIRTUAL in the Others column; in this case, of course, no address is required. The number of each virtual point will be assigned as follow. After having selected the VIRTUAL option, press OK. The group window will look like the following:

Now hold down the Shift button on the keyboard and double click with the mouse on the virtual LED to be assigned to a virtual point (be sure to click ON the LED).

A yellow label will be shown at the place of the clicked LED: type in a number in the range 1 to 2032 to assign that LED to the desired virtual point.

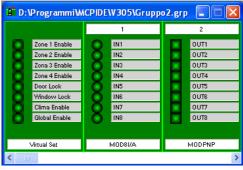

Click on the right side of each LED while holding down the Shift button on the keyboard to assign a label to the related point. Finally, click on the white band on the lower side of the virtual module (always holding down Shift button) to assign a name to it.

To check or to edit the virtual point assigned to a virtual LED, simply click again on the LED itself holding down Shift Key. The same operation allow to edit the other fields.

The result may be like the figure here on the right side.

For instance, add now a MOD8I/A and a MODPNP module to the same group as in the following figure. The write and edit operations described before (click while holding down the Shift key) can be performed on any kind of module in the group window. So use it to change the name assigned to each module (the white band on the lower side) or to change the address (the white band on the upper side).

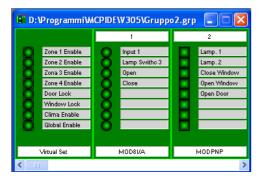

The color of the module symbols included in the groups can be:

GREY: that module was not configured in the current program

**RED:** the module does not answer to MCP 4

YELLOW: two or more modules have the same address

The 4 buttons in the group window allow to change the graphic mode. The first two modes will zoom in and zoom out; 4 zoom levels are available. The other two buttons act on the labels, showing or hiding them respectively.

The names of each input and output point were assigned in the same way described before (double click on the label on the right side of each LED).

The figure on this right side shows the option related to the graphical mode without labels and applied zoom level 3:

To remove a real or virtual module from a group, click on any area of the module itself while holding down the Alt button on the keyboard; a confirmation will be required before the deleting.

It is also possible to Copy and Paste a module in the same group or from a group to another one. To copy a module in the Clipboard, Click on any area of the module itself while holding down the Ctrl button on the keyboard. To paste

the module from the Clipboard to a group, press the button in the destination group.

To: D: Programmi MCPID... 

1 2

Virtual MOD8 MOD

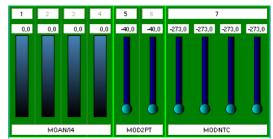

Each group can be saved (or updated) in a file by the button or by the related menu item and then reloaded by the button.

For analog modules, MCP VISIO allows the setting of the measurement scale. The figure on this right side shows 3 analog modules (MOAN/I4, MOD2PT e MODNTC) inside a group of MCP VISIO.

Each te4 box inside the graphic representation of the module is the values read from the field

Rel.: 1.2 October 2018

(or the simulated value). Clicking on these te4 boxes with the right button of the mouse, a window allowing to change the measurement scale setting appears; the values shown in this window depend on the considered module. For instance, clicking with right button on a te4 box of MOAN/I4 module, the window shown on this left side will appear; the zero value and the full scale value can be set in this window.

The Value/Bit is the achieved resolution using the currently setting of zero and full scale values. As shown, the default settings for this module are Zero Value = 0 and Full scale Value = 10.

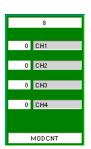

If the module is used to measure a pressure (through a proper transducer with 0÷10V output) in the range 1 bar (at 0V output) to 15 bar (at 10V output), then the settings required by MCP VISIO to show the read value in bar unit will be:

Zero Value = 1 Full scale Value = 15

The Value/Bit will be updated by the program according to the other two values.

For the "special" analog modules (e.g. MOD2PT and MODNTC) the scale setting should be left to the default value, because the measured parameters are well defined.

Regarding the counter modules MODCNT (see figure on this right side), it is possible to reset each one of the 4 counting values clicking on the related box te4 while holding down the Shift button on the keyboard.

## 10.3.2- The Projects of MCP VISIO

MCP VISIO allows to save all its current settings, intended as opened groups, windows, positions and dimensions of the windows, zoom levels and graphic levels, etc..

To create a project, press the button of MCP VISIO, or select the menu item Save project from the Visio menu.

To recall a previously saved project, press the button of MCP VISIO, or select the menu item Open Project from the Visio menu.

## 10.3.3- The Simulator of MCP VISIO

MCP VISIO features a simulator allowing to test and debug the MCP 4 program (or part of it). The simulator is a fully software tool, therefore no serial connection to MCP 4 is required.

The simulator shows the behavior of the output parameters of a program (e.g. real and virtual output points, registers, counters, etc.) as result of some stimulus on input parameters.

To activate the simulator select Run in the Simulator menu; select the file containing the program to be simulated (the file must have .BIN extension and it is automatically created by the compiling process of MCP IDE). Once loaded, the name of the file under simulation, together its path, will be shown in the status bar on the bottom side of MCP VISIO, together to the related controls Run, Stop, Reset and Reload.

While the simulation is running, its possible to change values, status of input modules, virtual points and so on; to do this, simply click on the object to be changed. For digital points (input modules, virtual points, etc.) the left button of the mouse performs the switching on, while the right button performs the switching off.

The Stop button stops the simulation while the Reset button restores all the parameters at their power up value (this is similar to the power up of MCP 4).

The Reload button reloads the file shown in the control panel; when changing anything in a program, it must be complied again and it must be reload in the simulator.

**DUEMMEGI** s.r.l. - Via Longhena, 4 – 20139 MILANO Tel. 02/57300377 - Fax 02/55213686 – www.duemmegi.it

## 11- MODBUS COMMUNICATION PROTOCOL

## 11.1- Abstract

MCP Plus can interface to external world through MODBUS RTU protocol. This protocol is integrated into MCP 4 and coexist, if enabled by the PROTOCOL directive (see related paragraph), together to the FXP XT proprietary protocol as described previously; this means:

- MCP Plus will answer according to the MODBUS protocol, if enabled, to any MODBUS requests
- MCP Plus will answer according to the proprietary FXP XT protocol to any FXP XT requests

This chapter will describe some traces about using of MODBUS protocol.

The communication parameters for MODBUS protocol implemented into MCP 4 are the followings:

- ▶ 1 start bit
- 8 data bits
- > no parity
- 1 or 2 stop bits (automatic detection)

The baud rate may be set as previously described to the following values: 2400, 4800, 9600, 19200, 38400, 57600, 115200 baud. **MCP 4 always acts as slave (it is a MODBUS peripheral unit)**; this means that it only answers to the requests of a MASTER MODBUS DEVICE.

In a MODBUS networks each peripheral device must its own address (normally named "station address"); the address of MCP 4 has to be set by the ADDRESS function as described in the related paragraph.

To localize the input and output points, virtual points, registers, etc., refer to the external RAM memory described in a previous chapter or, better, refer to the tables listed in the following pages.

# 11.2- Supported MODBUS functions

MCP 4 supports, in SLAVE mode, the following MODBUS functions:

| Function code | Description                       |
|---------------|-----------------------------------|
| 1             | Read output table                 |
| 2             | Read input table                  |
| 3             | Read registers (RAM memory)       |
| 4             | Read analog input                 |
| 5             | Force single digital output point |
| 6             | Preset single register            |
| 16            | Preset multiple registers         |
| 17            | Report device type                |

In MASTER mode, MCP 4 uses MODBUS functions 3, 4 and 16 only.

Rel.: 1.2 October 2018

# 11.3- Example of MODBUS functions

This paragraph shows some examples of MODBUS functions (request and answer) among the most used; in these paragraphs it is meant that MCP 4, in a MODBUS system, is a SLAVE device, thus it answers to the queries of a MASTER device.

The following examples are useful to identify the MODBUS functions to be used when communicating with MCP 4; the current MODBUS drivers implemented in many common devices (PLC, supervision software for PC, videoterminals, etc.) normally provide a development platform and a user interface which dramatically simplify the setting up in respect of the description that will be made in the following paragraphs. In practice

the setting up of the communication between the MASTER system and MCP 4 will be reduced to the configuration of the communication driver provided by the manufacturer of the MASTER system, therefore refer to the user's manual of the same system.

The following notations, unless otherwise specified, have to be intended in decimal format.

## 11.3.1- Function 1: Reading the digital output status

The MODBUS function 1 allows to read the output status; the following parameters must be specified:

• a start point (Start); this value must be multiple of 16. This value identifies the number of the digital output (normally called coil) starting from 16 and arranged by channel as follows:

| Output    | Number of the output (coil) |
|-----------|-----------------------------|
| Non usato | 0                           |
| 01:1.1    | 16                          |
| 02:1.1    | 32                          |
| •••       | • • •                       |
| 0127:1.1  | 2032                        |
| Non usato | 2048                        |
| 01:2.1    | 2064                        |
| 02:2.1    | 2080                        |
|           |                             |
| 0127:2.1  | 4080                        |
| Non usato | 4096                        |
| 01:3.1    | 4112                        |
| 02:3.1    | 4128                        |
|           |                             |
| 0127:3.1  | 6128                        |
| Non usato | 6144                        |
| 01:4.1    | 6160                        |
| 02:4.1    | 6176                        |
|           |                             |
| 0127:4.1  | 8176                        |

The general formula is: said **Add** the address of the real module of **CDITATTO** system, starting from which the status of the outputs has to be read and **CH** the channel, then the value of Start will be:

 $(Add \times 16) + 2048 \times (CH - 1)$ 

Allowed values: from 0 to 8176.

• how many output points have to be read (Number); in practice, how many modules having consecutive address have to be read. To avoid confusion, this value is suggested to be multiple of 16 and equal to the number of modules to be read multiplied by 16. Allowed values: from 16 to 8176.

#### MCP 4 will answer with a number of bytes equal to Number divided by 8.

## Example:

Read the output status of module 25, for instance a MOD8R that, as known, features 8 output points and a single channel (1). The parameters to be passed to MODBUS driver are:

Start: 400 Number: 16

MCP 4 will answer with 2 bytes containing the status of the output points of module 25, according to the binary code (1=out ON, 0=out OFF). The less significant bit of the lower byte is related to the output point 1, the most significant bit is related to the output point 8; the higher byte will be, in this case always 0x00 (zero).

## 11.3.2- Function 2: Reading the digital input status

The MODBUS function 2 allows to read the input status; the following parameters has to be specified:

• a start point (Start); this value must be multiple of 16. This value identifies the number of the digital input starting from 16 and arranged by channel as follows:

| Input     | Number of the input |
|-----------|---------------------|
| Non usato | 0                   |
| I1:1.1    | 16                  |
| 12:1.1    | 32                  |
|           |                     |
| I127:1.1  | 2032                |
| Non usato | 2048                |
| I1:2.1    | 2064                |
| 12:2.1    | 2080                |
|           | • • •               |
| I127:2.1  | 4080                |
| Non usato | 4096                |
| I1:3.1    | 4112                |
| 12:3.1    | 4128                |
|           |                     |
| I127:3.1  | 6128                |
| Non usato | 6144                |
| I1:4.1    | 6160                |
| 12:4.1    | 6176                |
|           | • • •               |
| I127:4.1  | 8176                |

The general formula is: said **Add** the address of the real module of **CDITHTTD** system, starting from which the status of the inputs has to be read and **CH** the channel, then the value of Start will be:

$$(Add x 16) + 2048 x (CH - 1)$$

Allowed values: from 0 to 8176.

• how many input points have to be read (Number); in practice, how many modules having consecutive address have to be read. To avoid confusion, this value is suggested to be multiple of 16 and equal to the number of modules to be read multiplied by 16. Allowed values: from 16 to 8176.

#### MCP 4 will answer with a number of bytes equal to Number divided by 8.

Rel.: 1.2 October 2018

#### Example 1:

Read the input status of module 43, for instance a MOD8I/A that, as known, features 8 input points and a single channel (1). The parameters to be passed to MODBUS driver are:

Start: 688 Number: 16

MCP 4 will answer with 2 bytes containing the status of the input points of module 43, according to the binary code (1=input ON, 0=input OFF). The less significant bit of the lower byte is related to the input point 1, the most significant bit is related to the input point 8; the higher byte will be, in this case always 0x00 (zero).

#### Example 2:

Read the input status of modules 57, 58, 59, and 60, for instance all MOD8I/A modules that, as known, features 8 input points each one. The parameters to be passed to MODBUS driver are:

**Start:** 912 **Number:** 64

MCP 4 will answer with 8 bytes containing the status of the input points of modules from 57 to 60 included.

### 11.3.3- Function 3: Reading the registers (RAM memory)

The MODBUS function 3 **is the most used**, because of general use, and it allows to read the content of the RAM memory of MCP 4 with all information about the status of the system. The following parameters have to be specified:

- a starting point (Start); this value is the address of the Word into the RAM starting from which the registers have to be read. Allowed values: from 1 to 30143 (in hexadecimal from 0x0001 to 0x75BF)
- how many Words have to be read (Number); allowed values: from 1 to 125.

MCP 4 will answer with a number of Words equal to the specified Number (that means a number of bytes equal to the double of the specified Number).

The MODBUS function 3 can be used to read the status of the real inputs and outputs, the status of virtual points, the content of counters, etc.; in practice, any information mapped into the MCP 4 RAM can be required, included the current date and time of the internal timekeeper.

#### Example 1:

Read the **output status** of module 25, for instance a MOD8R; alternatively to function 1, the function 3 can be used. The location of the Word in the RAM containing the status of the output module **i** (channel 1) is **i+512**, therefore, concerning the module 25, the following parameters will be passed to MODBUS driver:

Start: 537 Number: 1

MCP 4 will answer with a Word whose most significant byte is zero and the less significant byte is contains the status of the output points of module 25, in binary code (1=out ON, 0=out OFF). The less significant bit is related to the output point 1, the most significant bit is related to output point 8.

#### Example 2:

Read the **input status** of module 43, for instance a MOD8I/A; alternatively to function 2, the function 3 can be used. The location of the Word in the RAM containing the status of the input module **i** (channel 1) is **i**, therefore, concerning the module 43, the following parameters will be passed to MODBUS driver:

Start: 43 Number: 1

MCP 4 will answer with a Word whose most significant byte is zero and the less significant byte is contains the status of the input points of module 43, in binary code (1=input ON, 0=input OFF). The less significant bit is related to the input point 1, the most significant bit is related to input point 8.

#### Example 3:

Read the **input status** of module 57, 58, 59 and 60, for instance all MOD8I/A modules, using the function 3. The following parameters will be passed to MODBUS driver:

Start: 57 Number: 4

MCP 4 will answer with 4 Words (8 bytes), each one having the most significant byte equal to zero and the less significant byte containing the status of the input points of modules 57, 58, 59 and 60, in binary code (1=input ON, 0=input OFF). The less significant bit is related to the input point 1, the most significant bit is related to input point 8.

#### Example 4:

Read the status of virtual point V328 using the function 3. The Word containing the status of virtual point Vx is given by:

$$1153 + INT[(x - 1) / 16]$$

Since a virtual point takes only one bit of the Word, the bit number must be also specified; this is given by:

$$(x - 1)\%16$$

where the notation %16 means "module 16" and it is equivalent to the remainder of the division of x by 16; the notation INT[] means the integer part of the result of the operation inside the parenthesis.

To calculate y module 16 proceed as follows:

divide y by 16

•subtract the integer part of the result of point 1 to the result itself

•multiply by 16 the result of point 2: the resultant value is the module 16 of the starting number; this result is always an integer number in the range 0 to 7.

The parameters to be passed to the MODBUS driver, for virtual point V328, are:

Rel.: 1.2 October 2018

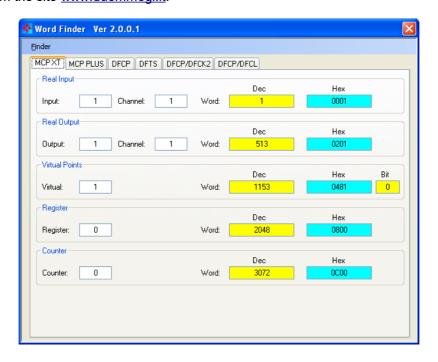

Start: 1173 Number: 1 7 Bit:

MCP 4 will answer with a Word (2 bytes) containing the status of the virtual points from V321 (less significant bit) to V336 (most significant bit). The virtual points are binary coded (1=point ON, 0=point OFF).

Example for the calculation of 327%16:

-327:16=20.4375-20.4375 - 20 = 0.4375 $-0.4375 \times 16 = 7$ 

Alternatively, the paragraph 11.4 reports some tables to easily locate the RAM address and the bits related to a given virtual point. As further possibility, use the program WordFinder (see the following figure) that can be free of charge from the site www.duemmegi.it.

### 11.3.4- Function 4: Reading analog inputs

The MODBUS function 4 is substantially equivalent to the function 3, therefore refer to this last one.

### 11.3.5- Function 5: Command of a single output digital point

The function 5 allows to force the status of a single output digital point, both real and virtual one; it is necessary to specify:

- REAL OUTPUT: the number of the real output point to be forced (Number); said i the address of the real module of **CONTATIO** system, a point of which has to be changed and said **p** the output point to be changed, then Number must be set to [(i -1) x 64 + p - 1] + (CH - 1) x 16. Allowed values for i range from 1 to 127, for **p** they range from 1 to 16 and for **CH** they range from 1 to 4.
- VIRTUAL OUPUT: the number of the output virtual point to be forced (Number); said n the number of the virtual point to be changed, then Number must be set to 16384 + n - 1. Allowed values for n range from 1 to 2032.
- new status of the output point (0xFF00=ON, 0x0000=OFF).

Switch on the point 3 (channel 1) of the output module addressed 29. The parameters to be passed to the MODBUS driver are:

Number: 1794 Status: 0xFF00

### 11.3.6- Function 6: Writing a single register (RAM memory)

The function 6 allows to write a value into a single Word of the RAM memory of MCP 4, that contains all information about the status of the system. The function 16 is more used than the function 6. The following parameters have to be specified:

- Number: this value is the Word address where the new value has to be written. Allowed values for Number: from 0 to 30143 (in hexadecimal from 0x0000 to 0x75BF).
- Data: the value to be written into the specified Word.

## 11.3.7- Function 16: Writing multiple registers (RAM memory)

The function 16 allows to write into the external RAM memory of MCP 4, that contains all information about the status of the system. This function, together to function 3, is the most used. The following parameters have to be specified:

- a starting point (Start); this value is the address of the RAM Word starting from which the new values have to be written. Allowed values for Start: from 0 to 30143 (in hexadecimal from 0x0000 to 0x75BF). The **internal memory** of the microcontroller MUST NOT BE MODIFIED.
- how many registers have to be written (Number); in practice, how many consecutive Words have to be written. Allowed values: from 1 to 125.
- the values to be written (Data) in the specified Words; each data (the amount is specified by Number) must be made by 2 bytes (1 WORD).

The MODBUS drivers normally provide the possibility to write one or more whole Words (useful for instance to change the content of a counter or to change an analog output), or to change a single bit of the Word (for instance to control a single real output or to change the status of a virtual point).

**DUEMMEGI** s.r.l. - Via Longhena, 4 – 20139 MILANO Rel.: 1.2 October 2018 Page 75 of 87

The MODBUS function 16 can thus be used to change the status of whole output module (both digital or analog type), the status of a single output point of a module, the status of virtual points, the content of counters, registers, etc.

To change a single bit of a register using the function 16, the status of the other bits of the same register has to be taken in account, because the writing takes place on the whole Word; in practice, the MODBUS driver automatically take in account this, because, when the writing must be at bit level, they execute the following steps:

- 1. reading, through the function 3, of the Word containing the bit to be changed
- 2. writing, through the function 16, of the just read Word read but with the wanted byte changed

The MODBUS function 16 can be also used to set the date and time of the internal timekeeper of MCP 4 as shown in one of the following examples.

#### Example 1:

Switch on the point 3 of the output module 29. Instead of function 5, the function 16 can be used. From the memory map of MCP 4 at paragraph 9.2.1 (or using WordFinder program, available free of charge on the site <a href="https://www.duemmegi.it">www.duemmegi.it</a>) the Word containing the status of output module 29 is the 541, therefore, regarding the module 29, the following parameters have to be passed to the MODBUS driver:

**Start:** 541

**Number:** 1 (normally, in this case, this parameter is not required by the driver)

Rel.: 1.2 October 2018

Bit: 2

Value: 1 (or ON, it depends on the used driver)

**Note:** the point 3 of an output module correspond to bit 2 of the Word, because the real output points of the **EDITITITID** system are numbered from 1 to 8, while the MODBUS driver "works" on the bits from 0 to 7.

The execution of this function, as described before, implies that the MODBUS driver read the Word 541 using the function 3, then it changes the bit 2 to the read value and finally it sends the resulting value to the Word 541 using the function 16. This procedure, normally, is automatically executed by the MODBUS driver of the MASTER system (PLC, supervision software, video-terminal, etc.).

#### Example 2:

Switch on all outputs of the output module 29. Use the function 16. The Word into MCP 4 RAM related to output module 29 (channel 1) is the 541, therefore the following parameters have to be passed to the MODBUS driver:

 Start:
 541

 Number:
 1

 Value:
 255

In this case the value 255 will be directly written into the Word 541. In addition, the MODBUS drivers allow to execute both mathematical and logical operations between the current value of the Word and a fixed value (for instance an EXOR between the current value of an output module and the value 255 to complement the status of each output of the same module) and then to write the result in the same Word.

### Example 3:

Switch on the virtual point V751 using the function 16. As said before for the function 3, the Word containing the status of virtual point  $\mathbf{V}\mathbf{x}$  is given by:

$$1153 + INT[(x - 1) / 16]$$

while the bit is:

$$(x - 1)\%16$$

As option, see the tables at the end of this manual or use the already mentioned program WordFinder.

The virtual point V751 is the bit 14 of the Word 1199; the following parameters have to be passed to the MODBUS driver:

**Start:** 1199

**Number:** 1 (normally, in this case, this parameter is not required by the driver)

Bit: 14

Value: 1 (or ON, it depends on the used driver)

The execution of this function, as described before, implies that the MODBUS driver read the Word 1199 using the function 3, then it changes the bit 14 to the read value and finally it sends the resulting value to the same Word 1199 using the function 16. This procedure is mandatory, because the Word 1199 contains the status of the virtual points from V737 to V752; since the status of the other virtual points does not be changed, then the preliminary reading of this Word is needed. This procedure, however, is normally executed automatically by the MODBUS driver of the MASTER system.

#### Example 4:

Write the value 157 into counter C22 (remember that, for the **EDITITIO** system, the counter are numbered from 0 to 1023). Use the function 16. The address of the Word containing the value of the counter **Cn** is given by **3072+n** (see RAM map or the tables at the end of this manual or use WordFinder); thus, concerning the counter C22, the following parameters have to be passed to the MODBUS driver:

 Start:
 3094

 Number:
 1

 Value:
 157

In this case the value 157 will be directly written into the Word 3094.

#### Example 5:

Set to 36 the minutes of the MCP 4 timekeeper; from the RAM map of MCP, the Word related to the minutes is the 1921. the following parameters have to be passed to the MODBUS driver:

 Start:
 1921

 Number:
 1

 Value:
 54

In this case the value 54 will be directly written into the Word 1921. The timekeeper will be updated with the new minutes value.

Note that the passed value is 54 (decimal), because the register of the minutes, as for all registers related to the timekeeper parameters, needs the BCD format; in facts, 36 in BCD format corresponds to 54 in decimal format.

### 11.4- Tables for relationship Words-Parameters of MCP 4

The following tables allow to quickly find the number of the MODBUS Word containing the wanted parameter. The following tables are valid if the directive PROTOCOL = (MODBUS) and not PROTOCOL = (MODBUS-) has been used (see description of the PROTOCOL directive). All numbers in the tables are in decimal format. As option, **DUEMMEGI** provides, free of charge, a small program named **WordFinder** which immediately gives the address of the MODBUS Word and the bit (if required) of the wanted parameter. This program can be downloaded fro the site <a href="https://www.duemmegi.it">www.duemmegi.it</a>, section Software Support.
